# THE EUCLIDEAN PLANE KINEMATICS 

El Said El Shinnawy<br>(Received April 22, 1977)

In his paper [1], A. Karger devoted himself to the study of the kinematic geometry in homogeneous spaces, the groups of motions of which are special 3-dimensional Lie groups. In what follows, I restrict myself to the Euclidean plane, but I am going to show a method leading to the solution of the equivalence problem for all Lie groups of motions. Besides this, I present all transitive one-parametric systems of motions in $E^{2}$.

Let $E^{2}$ denote the Euclidean plane, let $G$ be the Lie group of direct isometries of $E^{2}$ onto itself. By a motion we will understand a mapping $g: J \rightarrow G, J \subseteq \mathbb{R}$ being an interval. Our first problem may be formulated as follows: Let $g, \tilde{g}: J \rightarrow G$ be two motions; we have to find conditions which ensure the equivalence of $g$, $\tilde{g}$, i.e., the existence of a direct isometry $\sigma: E^{2} \rightarrow E^{2}$ such that $\sigma \circ g(t)=\tilde{g}(t)$ for each $t \in J$. We will solve this problem by constructing an invariant parameter and two "curvatures" on $g$; the desired condition will be then reduced to the equality of invariant parameters and curvatures. As a by-product, we will present a complete list of motions with constant curvatures.

Let $\left\{M, e_{1}, e_{2}\right\}$ be an orthonormal frame in $E^{2}$. Then a general direct isometry $g \in G$ is given by

$$
\begin{align*}
& g(M)=M+a e_{1}+b e_{2},  \tag{1}\\
& g\left(e_{1}\right)=\cos \alpha \cdot e_{1}-\sin \alpha \cdot e_{2}, \\
& g\left(e_{2}\right)=\sin \alpha \cdot e_{1}+\cos \alpha \cdot e_{2} .
\end{align*}
$$

Thus we may identify the group $G$ with the subgroup of $G L(3, \mathbb{R})$ of matrices of the form

$$
g=\left(\begin{array}{llc}
1 & a & b  \tag{2}\\
0 & \cos \alpha & -\sin \alpha \\
0 & \sin \alpha & \cos \alpha
\end{array}\right) .
$$

The Lie algebra $\mathfrak{G}$ is then, as is easy to see, identified with the Lie algebra of matrices of the form
(3)

$$
V=\left(\begin{array}{ll}
0 & \mathrm{~d} a / \mathrm{d} t
\end{array} \mathrm{~d} b / \mathrm{d} t\right)
$$

let
(4)

$$
V_{1}=\left(\begin{array}{lll}
0 & 1 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{array}\right), \quad V_{2}=\left(\begin{array}{lll}
0 & 0 & 1 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{array}\right), \quad V_{3}=\left(\begin{array}{rrr}
0 & 0 & 0 \\
0 & 0 & -1 \\
0 & 1 & 0
\end{array}\right)
$$

be its basis. Then

$$
\begin{equation*}
\left[V_{1}, V_{2}\right]=0, \quad\left[V_{1}, V_{3}\right]=-V_{2}, \quad\left[V_{2}, V_{3}\right]=V_{1} . \tag{5}
\end{equation*}
$$

Now, let $g: J \rightarrow G, g=g(t)$ be a motion. Then we get a mapping $v: J \rightarrow \mathfrak{G}$ given by

$$
\begin{equation*}
v(t)=g(t)^{-1} \frac{\mathrm{~d} g(t)}{\mathrm{d} t} . \tag{6}
\end{equation*}
$$

Taking into consideration (1), the motion $g(t)$ is represented by the equations

$$
\begin{equation*}
\alpha=\alpha(t), \quad a=a(t), \quad b=b(t) ; \quad t \in J . \tag{7}
\end{equation*}
$$

It is easy to see that

$$
\begin{equation*}
v(t)=\left(\frac{\mathrm{d} a}{\mathrm{~d} t}-b \frac{\mathrm{~d} \alpha}{\mathrm{~d} t}\right) V_{1}+\left(\frac{\mathrm{d} b}{\mathrm{~d} t}+a \frac{\mathrm{~d} \alpha}{\mathrm{~d} t}\right) V_{2}+\frac{\mathrm{d} \alpha}{\mathrm{~d} t} V_{3} \tag{8}
\end{equation*}
$$

With the second motion $\tilde{g}: J \rightarrow G$, we associate similarly the mapping $\tilde{v}$. Let $\operatorname{In}(\tilde{G})$ denote the Lie group of inner automorphisms of $\mathfrak{G}$. Then it is known that $g$ and $\tilde{g}$ are equivalent if and only if there is a $\Gamma_{0} \in \operatorname{In}(\mathfrak{G})$ such that $\tilde{v}(t)=\Gamma_{0}\{v(t)\}$ for each $t \in J$. Because the motion $g(t)$ is given, up to the equivalence, by $v(t)$, our problem reduces to the equivalence problem for two mappings $v, \tilde{v}: J \rightarrow(\mathfrak{5}$ with respect to the group $\operatorname{In}(\mathfrak{5})$. We are now going to solve this problem even with respect to a more general group Aut ( $\mathfrak{( 5 )}$ ) of all automorphisms of $\mathfrak{G}$.

Let $\Gamma \in \operatorname{Aut}(5)$ be given by

$$
\begin{align*}
& \Gamma\left(V_{1}\right)=a_{1} V_{1}+a_{2} V_{2}+a_{3} V_{3},  \tag{9}\\
& \Gamma\left(V_{2}\right)=b_{1} V_{1}+b_{2} V_{2}+b_{3} V_{3}, \\
& \Gamma\left(V_{3}\right)=c_{1} V_{1}+c_{2} V_{2}+c_{3} V_{3} .
\end{align*}
$$

From

$$
\begin{gather*}
{\left[\Gamma\left(V_{1}\right), \Gamma\left(V_{2}\right)\right]=0, \quad\left[\Gamma\left(V_{1}\right), \Gamma\left(V_{3}\right)\right]=-\Gamma\left(V_{2}\right),}  \tag{10}\\
{\left[\Gamma\left(V_{2}\right), \Gamma\left(V_{3}\right)\right]=\Gamma\left(V_{1}\right)}
\end{gather*}
$$

we see that Aut $(\mathbb{6}) \subset G L(3, \mathbb{R})$ may be identified with the set of all matrices of the form

$$
\left(\begin{array}{rrr}
a_{1} & a_{2} & 0  \tag{11}\\
-a_{2} & a_{1} & 0 \\
c_{1} & c_{2} & 1
\end{array}\right) \text { and }\left(\begin{array}{rrr}
a_{1} & a_{2} & 0 \\
a_{2} & -a_{1} & 0 \\
c_{1} & c_{2} & 1
\end{array}\right) \text { with } a_{1}^{2}+a_{2}^{2} \neq 0 .
$$

Of course, the Lie algebra $\mathfrak{A t t}(\mathfrak{F}) \subset \mathfrak{G} \mathfrak{L}(3, \mathbb{R})$ of Aut $(\mathfrak{G})$ is the set of all matrices of the form

$$
\left(\begin{array}{rrr}
\alpha_{1} & \alpha_{2} & 0  \tag{12}\\
-\alpha_{2} & \alpha_{1} & 0 \\
\beta_{1} & \beta_{2} & 0
\end{array}\right) .
$$

It is known that the Lie algebra $\mathfrak{I n}(\mathfrak{G})$ is the set of all homomorphisms ad $u:(\mathfrak{G} \rightarrow(\mathfrak{G}$, $u \in \mathfrak{G}$. For $u=u^{1} V_{1}+u^{2} V_{2}+u^{3} V_{3}$, we have

$$
\begin{equation*}
\operatorname{ad}(u)\left(x^{1} V_{1}+x^{2} V_{2}+x^{3} V_{3}\right)=x^{1} u^{3} V_{2}-x^{2} u^{3} V_{1}-x^{3}\left(u^{1} V_{2}-u^{2} V_{1}\right), \tag{13}
\end{equation*}
$$

i.e., we may identify $\mathfrak{I n}(\mathfrak{G}) \subset \mathfrak{A} \mathfrak{u t}(\mathfrak{G})$ with the set of all matrices of the form

$$
\left(\begin{array}{ccc}
0 & u^{3} & 0  \tag{14}\\
-u^{3} & 0 & 0 \\
u^{2} & -u^{1} & 0
\end{array}\right) .
$$

From this (or by a direct calculation) we get that $\operatorname{In}(\mathfrak{G}) \subset$ Aut $(\mathfrak{G})$ is the group of all matrices (11) with $a_{1}^{2}+a_{2}^{2}=1$, i.e., its identity component is the group of all matrices of the form

$$
\left(\begin{array}{rrr}
\cos \psi_{1} & \sin \psi_{1} & 0  \tag{15}\\
-\sin \psi_{1} & \cos \psi_{1} & 0 \\
\psi_{2} & \psi_{3} & 1
\end{array}\right) .
$$

First of all, let us study the mapping $v: J \rightarrow \mathfrak{G}$ with respect to the group $\operatorname{In}(\mathfrak{G})$ acting on $\mathfrak{G}$. By a frame of $\mathfrak{G}$ (with respect to this group) we shall mean each triple $\left\{v_{1}, v_{2}, v_{3}\right\}$ such that $v_{i}=\Gamma_{0}\left(V_{i}\right)$ for a $\Gamma_{0} \in \operatorname{In}(\mathfrak{5})$ and $i=1,2,3$. If $\left\{v_{1}, v_{2}, v_{3}\right\}$ and $\left\{w_{1}, w_{2}, w_{3}\right\}$ are two frames, then there are $\varphi, \lambda, \mu$ such that

$$
\begin{align*}
& w_{1}=\cos \varphi \cdot v_{1}+\sin \varphi \cdot v_{2},  \tag{16}\\
& w_{2}=-\sin \varphi \cdot v_{1}+\cos \varphi \cdot v_{2}, \\
& w_{3}=\quad \lambda \cdot v_{1}+\mu \cdot v_{2}+v_{3} .
\end{align*}
$$

Let $\left\{v_{1}(t), v_{2}(t), v_{3}(t)\right\}, t \in J$ be a field of frames. Then there are functions $\alpha_{i}^{j}(t)$ such that

$$
\begin{equation*}
\frac{\mathrm{d} v_{i}(t)}{\mathrm{d} t}=\alpha_{i}^{j}(t) \cdot v_{j}(t), \tag{17}
\end{equation*}
$$

but (14) implies that (17) should have the form

$$
\begin{equation*}
\frac{\mathrm{d} v_{1}}{\mathrm{~d} t}=\beta v_{2}, \quad \frac{\mathrm{~d} v_{2}}{\mathrm{~d} t}=-\beta v_{1}, \quad \frac{\mathrm{~d} v_{3}}{\mathrm{~d} t}=\gamma_{1} v_{1}+\gamma_{2} v_{2} . \tag{18}
\end{equation*}
$$

Consider $v=v(t), t \in J$, and suppose of course $v(t) \neq 0$ for each $t \in J$. With each $t$, let us associate a frame $\left\{v_{1}(t), v_{2}(t), v_{3}(t)\right\}$ such that $v_{3}(t)$ and $v(t)$ are dependent; this can always be achieved because of (15) by a suitable choice of $\psi_{2}, \psi_{3}$. Any other field of frames $\left\{w_{1}(t), w_{2}(t), w_{3}(t)\right\}$ with the same property is given by

$$
\begin{align*}
& w_{1}=\cos \varphi \cdot v_{1}+\sin \varphi \cdot v_{2},  \tag{19}\\
& w_{2}=-\sin \varphi \cdot v_{1}+\cos \varphi \cdot v_{2}, \\
& w_{3}=
\end{align*}
$$

For $\left\{w_{1}(t), w_{2}(t), w_{3}(t)\right\}$, we may write equations similar to (18):

$$
\begin{equation*}
\frac{\mathrm{d} w_{1}}{\mathrm{~d} t}=\tilde{\beta} w_{2}, \quad \frac{\mathrm{~d} w_{2}}{\mathrm{~d} t}=-\tilde{\beta} w_{1}, \quad \frac{\mathrm{~d} w_{3}}{\mathrm{~d} t}=\tilde{\gamma}_{1} w_{1}+\tilde{\gamma}_{2} w_{2} . \tag{20}
\end{equation*}
$$

From the equations (18)-(20) we obtain
(21) $\frac{\mathrm{d} \varphi}{\mathrm{d} t} \cdot \sin \varphi+\beta \cdot \sin \varphi=\tilde{\beta} \cdot \sin \varphi, \frac{\mathrm{d} \varphi}{\mathrm{d} t} \cdot \cos \varphi+\beta \cdot \cos \varphi=\tilde{\beta} \cdot \cos \varphi$,

$$
\tilde{\gamma}_{1} \cdot \cos \varphi-\tilde{\gamma}_{2} \cdot \sin \varphi=\gamma_{1}, \quad \tilde{\gamma}_{1} \cdot \sin \varphi+\tilde{\gamma}_{2} \cdot \cos \varphi=\gamma_{2} .
$$

From $\left(21_{3,4}\right)$ we get

$$
\begin{equation*}
\gamma_{1}^{2}+\gamma_{2}^{2}=\tilde{\gamma}_{1}^{2}+\tilde{\gamma}_{2}^{2}, \tag{22}
\end{equation*}
$$

and $\gamma_{1}^{2}+\gamma_{2}^{2}$ is thus an invariant of our system of frames. We have to distinguish two cases. Let us, first of all, consider the case

$$
\begin{equation*}
\gamma_{1}=\gamma_{2}=0 . \tag{23}
\end{equation*}
$$

The equations $\left(21_{1,2}\right)$ reduce to

$$
\begin{equation*}
\frac{\mathrm{d} \varphi}{\mathrm{~d} t}+\beta=\tilde{\beta}, \tag{24}
\end{equation*}
$$

and we may choose, at least locally, $\varphi(t)$ in such a way that $\tilde{\beta}=0$. Thus we may associate with $v(t)$ a field of frames such that

$$
\begin{equation*}
\frac{\mathrm{d} v_{1}}{\mathrm{~d} t}=0, \quad \frac{\mathrm{~d} v_{2}}{\mathrm{~d} t}=0, \quad \frac{\mathrm{~d} v_{3}}{\mathrm{~d} t}=0 \tag{25}
\end{equation*}
$$

i.e., $v(t)$ reduces to a fixed line and $g(t)$ may be parametrized in such a way that it becomes a one-parametric subgroup of $G$. Let us suppose

$$
\begin{equation*}
\gamma_{1}^{2}+\gamma_{2}^{2} \neq 0 . \tag{26}
\end{equation*}
$$

It is easy to see that we may then choose the frames restricted by the condition

$$
\begin{equation*}
\gamma_{2}=0 ; \tag{27}
\end{equation*}
$$

from (21) we get

$$
\begin{equation*}
\tilde{\beta}=\beta, \quad \tilde{\gamma}_{1}=\gamma_{1}, \tag{28}
\end{equation*}
$$

$\beta$ and $\gamma_{1}$ being thus the invariants of $v(t)$. From (19) we see that the condition (27) associates with $v(t)$ just one field of frames.

Let us now determine explicitly the invariants of our initial motion (7). For

$$
\begin{equation*}
A(t)=\frac{\mathrm{d} a}{\mathrm{~d} t}-b \frac{\mathrm{~d} \alpha}{\mathrm{~d} t}, \quad B(t)=\frac{\mathrm{d} b}{\mathrm{~d} t}+a \frac{\mathrm{~d} \alpha}{\mathrm{~d} t}, \quad C(t)=\frac{\mathrm{d} \alpha}{\mathrm{~d} t}, \tag{29}
\end{equation*}
$$

(8) takes the form

$$
\begin{equation*}
v(t)=A(t) \cdot V_{1}+B(t) \cdot V_{2}+C(t) \cdot V_{3} . \tag{30}
\end{equation*}
$$

It is not necessary to study the case $C(t)=0$; in this case $\alpha=$ constant, and our motion consists just of a group of translations. Thus we may suppose

$$
\begin{equation*}
C(t) \neq 0 \quad \text { for } \quad t \in J \tag{31}
\end{equation*}
$$

The general field of frames associated with $v(t)$ is then

$$
\begin{align*}
& v_{1}(t)=\cos \xi(t) \cdot V_{1} \quad+\sin \xi(t) \cdot V_{2},  \tag{32}\\
& v_{2}(t)=-\sin \xi(t) \cdot V_{1} \quad+\cos \xi(t) \cdot V_{2}, \\
& v_{3}(t)=A(t) \cdot C(t)^{-1} \cdot V_{1}+B(t) \cdot C(t)^{-1} \cdot V_{2}+V_{3}
\end{align*}
$$

and we get

$$
\begin{gather*}
\frac{\mathrm{d} v_{1}}{\mathrm{~d} t}=\frac{\mathrm{d} \xi}{\mathrm{~d} t} \cdot v_{2}, \quad \frac{\mathrm{~d} v_{2}}{\mathrm{~d} t}=-\frac{\mathrm{d} \xi}{\mathrm{~d} t} \cdot v_{1},  \tag{33}\\
\frac{\mathrm{~d} v_{3}}{\mathrm{~d} t}=\left\{\frac{\mathrm{d}}{\mathrm{~d} t}\left(A C^{-1}\right) \cdot \cos \xi+\frac{\mathrm{d}}{\mathrm{~d} t}\left(B C^{-1}\right) \cdot \sin \xi\right\} v_{1}+ \\
+\left\{-\frac{\mathrm{d}}{\mathrm{~d} t}\left(A C^{-1}\right) \cdot \sin \xi+\frac{\mathrm{d}}{\mathrm{~d} t}\left(B C^{-1}\right) \cdot \cos \xi\right\} v_{2} .
\end{gather*}
$$

According to our previous discussion, we may choose $\xi(t)$ in such a way that

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} t}\left(A C^{-1}\right) \cdot \sin \xi-\frac{\mathrm{d}}{\mathrm{~d} t}\left(B C^{-1}\right) \cdot \cos \xi=0 \tag{34}
\end{equation*}
$$

the functions

$$
\begin{equation*}
\frac{\mathrm{d} \xi}{\mathrm{~d} t}, \quad \frac{\mathrm{~d}}{\mathrm{~d} t}\left(A C^{-1}\right) \cdot \cos \xi+\frac{\mathrm{d}}{\mathrm{~d} t}\left(B C^{-1}\right) \cdot \sin \xi \tag{35}
\end{equation*}
$$

being then the invariants of our motion. For $g(t)$ we may introduce a canonical parameter by the condition $v(t)=v_{3}(t)$, i.e., $C(t)=1$; from (29) we see that $t=$ $=\alpha+$ const. From now on, let us use the canonical parameter $\alpha$. Define $\varrho$ by

$$
\begin{equation*}
\varrho=\left\{\left(\frac{\mathrm{d} A}{\mathrm{~d} \alpha}\right)^{2}+\left(\frac{\mathrm{d} B}{\mathrm{~d} \alpha}\right)^{2}\right\}^{1 / 2} \tag{36}
\end{equation*}
$$

The case $\varrho=0$ corresponds to (23). Therefore, let us suppose $\varrho \neq 0$. To get the invariants, we have to choose

$$
\begin{equation*}
\sin \xi=\varrho^{-1} \cdot \frac{\mathrm{~d} B}{\mathrm{~d} \alpha}, \quad \cos \xi=\varrho^{-1} \cdot \frac{\mathrm{~d} A}{\mathrm{~d} \alpha} \tag{37}
\end{equation*}
$$

and we see that the invariants (35) take the final form

$$
\begin{gather*}
J_{1}=\left\{\left(\frac{\mathrm{d}}{\mathrm{~d} \alpha}\left(\varrho^{-1} \cdot \frac{\mathrm{~d} B}{\mathrm{~d} \alpha}\right)\right)^{2}+\left(\frac{\mathrm{d}}{\mathrm{~d} \alpha}\left(\varrho^{-1} \cdot \frac{\mathrm{~d} A}{\mathrm{~d} \alpha}\right)\right)^{2}\right\}^{1 / 2}  \tag{38}\\
J_{2}=\left\{\left(\frac{\mathrm{d} A}{\mathrm{~d} \alpha}\right)^{2}+\left(\frac{\mathrm{d} B}{\mathrm{~d} \alpha}\right)^{2}\right\}^{1 / 2}
\end{gather*}
$$

Let us turn our attention to the study of motions with constant invariants. First of all, let us study the case $\varrho=J_{2}=0$.

Introduce the functions $r, s: J \rightarrow \mathbb{C}$ by

$$
\begin{equation*}
r(\alpha)=a(\alpha)+i b(\alpha), \quad s(\alpha)=\frac{\mathrm{d} r(\alpha)}{\mathrm{d} \alpha}+i r(\alpha) . \tag{39}
\end{equation*}
$$

Then it is easy to see that

$$
\begin{equation*}
J_{2}=\left|\frac{\mathrm{d} s}{\mathrm{~d} \alpha}\right| . \tag{40}
\end{equation*}
$$

$J_{2}=0$ implies the existence of $\varkappa_{1} \in \mathbb{C}$ such that

$$
\begin{equation*}
\frac{\mathrm{d} r}{\mathrm{~d} \alpha}+i r=x_{1} . \tag{41}
\end{equation*}
$$

The general solution of this equation is then

$$
\begin{equation*}
r=x_{2} \mathrm{e}^{-i \alpha}-i x_{1}, \quad x_{2} \in \mathbb{C} . \tag{42}
\end{equation*}
$$

In $E^{2}$, introduce the coordinates $(x, y)$ of a point $X$ with respect to the basis $\left\{M, e_{1}, e_{2}\right\}$ by means of $X=M+x e_{1}+y e_{2}$. By $g \in G(1)$, this point is mapped onto the point $g(X)=g(M)+x g\left(e_{1}\right)+y g\left(e_{2}\right)$; let it have coordinates $x^{*}, y^{*}$. Then

$$
\begin{equation*}
x^{*}=\cos \alpha \cdot x+\sin \alpha \cdot y+a, \quad y^{*}=-\sin \alpha \cdot x+\cos \alpha \cdot y+b, \tag{43}
\end{equation*}
$$

$$
z^{*}=e^{-i \alpha} \cdot z+r ; \quad z=x+i y, \quad z^{*}=x^{*}+i y^{*} .
$$

Thus our $g(\alpha)$ associates with the point $z$ the point

$$
\begin{equation*}
z^{*}=e^{-i \alpha}\left(z+\chi_{2}\right)-i \chi_{1} . \tag{45}
\end{equation*}
$$

Suppose that the canonical parameter is chosen in such a way that $g(0)$ is the identity mapping. Then $x_{2}=i \varkappa_{1}$ and the motion is given by ( $火=x_{2}$ )

$$
\begin{equation*}
z^{*}=e^{-i x}(z+x)-x . \tag{46}
\end{equation*}
$$

Hence

$$
\begin{equation*}
\left|z^{*}+x\right|=|z+x| \tag{47}
\end{equation*}
$$

and we see that the motion considered is just the rotation around the point $-x$.
Let us now consider the case

$$
\begin{equation*}
J_{2}=\text { constant } \neq 0 . \tag{48}
\end{equation*}
$$

It is not difficult to see that (48) implies

$$
\begin{equation*}
J_{1}=J_{2}^{-1}\left|\frac{\mathrm{~d}^{2} s}{\mathrm{~d} \alpha^{2}}\right| . \tag{49}
\end{equation*}
$$

First of all, let

$$
\begin{equation*}
J_{1}=0, \tag{50}
\end{equation*}
$$

i.e.,

$$
\begin{equation*}
s=\varrho_{1} \alpha+\varrho_{2} ; \quad \varrho_{1}, \varrho_{2} \in \mathbb{C} . \tag{51}
\end{equation*}
$$

The general solution of the differential equation

$$
\begin{equation*}
\frac{\mathrm{d} r}{\mathrm{~d} \alpha}+i r=\varrho_{1} \alpha+\varrho_{2} \tag{52}
\end{equation*}
$$

is

$$
\begin{equation*}
r=\varrho_{3} e^{-i \alpha}-i \varrho_{1} \alpha+\varrho_{1}-i \varrho_{2} ; \quad \varrho_{3} \in \mathbb{C} ; \tag{53}
\end{equation*}
$$

and our motion is given by (44), i.e.,

$$
\begin{equation*}
z^{*}=e^{-i \alpha}\left(z+\varrho_{3}\right)-i \varrho_{1} \alpha+\varrho_{1}-i \varrho_{2} . \tag{54}
\end{equation*}
$$

Let us suppose $g(0)$ to be identity. Then $\varrho_{3}+\varrho_{1}-i \varrho_{2}=0$ and (54) reduces to

$$
\begin{equation*}
z^{*}=e^{-i \alpha}(z+\varrho)-i \varrho_{1} \alpha-\varrho ; \varrho=\varrho_{3} \in \mathbb{C} ; \tag{55}
\end{equation*}
$$

of course, $J_{2}=\left|\varrho_{1}\right|$. Let us calculate the centroids of (55). The fixed centroid is the set of points $z_{0}(\alpha)$ such that $\left(\mathrm{d} z^{*} / \mathrm{d} \alpha\right)=0$, i.e., it is given by $z_{0}=-\varrho_{1} e^{i \alpha}-\varrho$. Because of $\left|z_{0}+\varrho\right|=\left|\varrho_{1}\right|$, we see that it is a circle with the center $-\varrho$ and the radius $J_{2}$. The moving centroid is then given by $z^{*}=e^{-i \alpha}\left(z_{0}+\varrho\right)-i \varrho_{1} \alpha-\varrho=-i \varrho_{1} \alpha-$ $-\varrho_{1}-\varrho$, and it is the straight line with the equation

$$
\begin{equation*}
\bar{\varrho}_{1} z+\varrho_{1} \bar{z}+\varrho \varrho_{1}+\varrho_{1} \bar{\varrho}+2 \varrho_{1} \bar{\varrho}_{1}=0 . \tag{56}
\end{equation*}
$$

Thus our motion is produced by rolling a straight line upon a circle of radius $J_{2}$.
Let us turn our attention to the case

$$
\begin{equation*}
J_{1}=\text { constant } \neq 0, \quad J_{2}=\text { constant } \neq 0 . \tag{57}
\end{equation*}
$$

The function $s(\alpha)$ should then be the solution of the differential equations (see (49))

$$
\begin{equation*}
\left|\frac{\mathrm{d} s}{\mathrm{~d} \alpha}\right|=J_{2}, \quad\left|\frac{\mathrm{~d}^{2} s}{\mathrm{~d} \alpha^{2}}\right|=J_{1} J_{2} . \tag{58}
\end{equation*}
$$

From (581) we get

$$
\begin{equation*}
\frac{\mathrm{d} s}{\mathrm{~d} \alpha} \cdot \frac{\mathrm{~d}^{2} \bar{s}}{\mathrm{~d} \alpha^{2}}+\frac{\mathrm{d} \bar{s}}{\mathrm{~d} \alpha} \cdot \frac{\mathrm{~d}^{2} s}{\mathrm{~d} \alpha^{2}}=0 \tag{59}
\end{equation*}
$$

Multiplying this by

$$
\frac{\mathrm{d} s}{\mathrm{~d} \alpha} \cdot \frac{\mathrm{~d}^{2} s}{\mathrm{~d} \alpha^{2}}
$$

and inserting from (58), we have

$$
\begin{equation*}
J_{2}^{2}\left(\frac{\mathrm{~d}^{2} s}{\mathrm{~d} \alpha^{2}}\right)^{2}+J_{土}^{2} J_{2}^{2}\left(\frac{\mathrm{~d} s}{\mathrm{~d} \alpha}\right)^{2}=0 \tag{60}
\end{equation*}
$$

i.e.,

$$
\begin{equation*}
\frac{\mathrm{d}^{2} s}{\mathrm{~d} \alpha^{2}}=-\varepsilon i J_{1} \cdot \frac{\mathrm{~d} s}{\mathrm{~d} \alpha} ; \quad \varepsilon= \pm 1 \tag{61}
\end{equation*}
$$

The general solution of this equation is

$$
\begin{equation*}
s=\varepsilon i \chi_{1} J_{1}^{-1} e^{-\varepsilon i J_{1} \alpha}+\chi_{2}, \quad \chi_{1}, \varkappa_{2} \in \mathbb{C} . \tag{62}
\end{equation*}
$$

From (581) we obtain

$$
\begin{equation*}
\left|\varkappa_{1}\right|=J_{2} . \tag{63}
\end{equation*}
$$

Now, the general solution of $(\mathrm{d} r / \mathrm{d} \alpha)+i r=s($ see (39)) is

$$
\begin{equation*}
r=\varepsilon \varkappa_{1} J_{1}^{-1}\left(1-\varepsilon J_{1}\right)^{-1} e^{-\varepsilon i J_{1} \alpha}+\varkappa_{3} e^{-i \alpha}-i \chi_{2} ; \quad \chi_{3} \in \mathbb{C} \tag{64}
\end{equation*}
$$

in the case

$$
\begin{equation*}
\varepsilon J_{1} \neq 1 ; \tag{65}
\end{equation*}
$$

the case $\varepsilon J_{1}=1$ will be considered later on. The motion $g(\alpha)$ is then (see (44))

$$
\begin{equation*}
z^{*}=\left(z+\chi_{3}\right) e^{-i \alpha}+\varepsilon \chi_{1} J_{1}^{-1}\left(1-\varepsilon J_{1}\right)^{-1} e^{-\varepsilon i J_{1} \alpha}-i \chi_{2} . \tag{66}
\end{equation*}
$$

The condition $g(0)=$ identity implies $\chi_{3}-i \varkappa_{2}+\varepsilon \chi_{1} J_{1}^{-1}\left(1-\varepsilon J_{1}\right)^{-1}=0$, and we get

$$
\begin{equation*}
z^{*}=\left(z+\chi_{3}\right) e^{-i \alpha}+\varepsilon \chi_{1} J_{1}^{-1}\left(1-\varepsilon J_{1}\right)^{-1}\left(e^{-\varepsilon i J_{1} \alpha}-1\right)-\chi_{3} . \tag{67}
\end{equation*}
$$

It is easy to see that the fixed centroid is given by

$$
\begin{equation*}
z+x_{3}=-x_{1}\left(1-\varepsilon J_{1}\right)^{-1} e^{i\left(1-\varepsilon J_{1}\right) \alpha}, \tag{68}
\end{equation*}
$$

and it is a circle $C_{F}$, its center $S_{F}$ and its radius $R_{F}$ being given by

$$
\begin{equation*}
S_{F}=-\varkappa_{3}, \quad R_{F}=J_{2}\left|1-\varepsilon J_{1}\right|^{-1} . \tag{69}
\end{equation*}
$$

The moving centroid is then

$$
\begin{equation*}
z+\varepsilon \chi_{1} J_{1}^{-1}\left(1-\varepsilon J_{1}\right)^{-1}+\chi_{3}=\varepsilon \chi_{1} J_{1}^{-1} e^{-\varepsilon i J_{1} \alpha} ; \tag{70}
\end{equation*}
$$

it is a circle $C_{M}$ with

$$
\begin{equation*}
S_{M}=-\varkappa_{3}-\varepsilon \varkappa_{1} J_{1}^{-1}\left(1-\varepsilon J_{1}\right)^{-1}, \quad R_{M}=J_{1}^{-1} J_{2} . \tag{71}
\end{equation*}
$$

It remains to consider the case $\varepsilon J_{1}=1$. Because of $J_{1}>0$, we have

$$
\begin{equation*}
J_{1}=1, \quad \varepsilon=1 \tag{72}
\end{equation*}
$$

and (62) reduces to

$$
\begin{equation*}
s=i \chi_{1} e^{-i \alpha}+\chi_{2}, \quad \chi_{1}, \varkappa_{2} \in \mathbb{C} . \tag{73}
\end{equation*}
$$

Hence

$$
\begin{equation*}
r=\left(i x_{1} \alpha+\varkappa_{3}\right) e^{-i \alpha}-i \varkappa_{2} \tag{74}
\end{equation*}
$$

and

$$
\begin{equation*}
z^{*}=\left(z+i x_{1} \alpha+x_{3}\right) e^{-i \alpha}-i \chi_{2} . \tag{75}
\end{equation*}
$$

The condition $g(0)=$ identity implies $x_{3}-i x_{2}=0$, i.e.,

$$
\begin{equation*}
z^{*}=\left(z+i x_{1} \alpha+x_{3}\right) e^{-i \alpha}-x_{3} . \tag{76}
\end{equation*}
$$

The fixed centroid is then

$$
\begin{equation*}
z=-i x_{1} \alpha+x_{1}-x_{3}, \tag{77}
\end{equation*}
$$

i.e., a straight line with the equation (see (63))

$$
\begin{equation*}
\bar{x}_{1} z+x_{1} \bar{z}-2 J_{2}^{2}+x_{1} \bar{x}_{3}+\bar{x}_{1} x_{3}=0 . \tag{78}
\end{equation*}
$$

The moving centroid is

$$
\begin{equation*}
z=x_{1} e^{-i \alpha}-x_{3}, \tag{79}
\end{equation*}
$$

and it is a circle with $S_{M}=-\varkappa_{3}, R_{M}=J_{2}$.
The summary of our results is contained in the following
Theorem 1. Let $g(\alpha)$ be a motion in $E^{2}$ with constant invariants $J_{1}, J_{2}$. Then it is the so-called planetary motion, i.e., it is produced by rolling a circle $C_{M}$ upon a fixed circle $C_{F}$. In the case $J_{2}=0$ both circles degenerate to one point, and $g(\alpha)$ is just the rotation around this point. In the case $J_{1}=0, J_{2} \neq 0, C_{M}$ becomes a straight line; in the case $J_{1}=\varepsilon=1, J_{2} \neq 0, C_{F}$ is a straight line.

Finally, let us study the invariants of our motion with respect to the group Aut ((G)). By a frame we call now each triple $\left\{v_{i}\right\}$ such that $v_{i}=\Gamma\left(V_{i}\right), \Gamma \in$ Aut ( $(\mathfrak{G})$. With $v(t)$ let us associate a frame $\left\{v_{1}(t), v_{2}(t), v_{3}(t)\right\}$ such that $v_{3}(t)$ and $v(t)$ are dependent. Then (see (12))

$$
\begin{equation*}
\frac{\mathrm{d} v_{1}}{\mathrm{~d} t}=\alpha_{1} v_{1}+\alpha_{2} v_{2}, \quad \frac{\mathrm{~d} v_{2}}{\mathrm{~d} t}=-\alpha_{2} v_{1}+\alpha_{1} v_{2}, \quad \frac{\mathrm{~d} v_{3}}{\mathrm{~d} t}=\beta_{1} v_{1}+\beta_{2} v_{2} \tag{80}
\end{equation*}
$$

and the possible changes of the frames are given by

$$
\begin{equation*}
w_{1}=a_{1} v_{1}+a_{2} v_{2}, \quad w_{2}=-a_{2} v_{1}+a_{1} v_{2}, \quad w_{3}=v_{3} ; \quad a_{1}^{2}+a_{2}^{2} \neq 0 . \tag{81}
\end{equation*}
$$

For

$$
\begin{equation*}
\frac{\mathrm{d} w_{1}}{\mathrm{~d} t}=\tilde{\alpha}_{1} w_{1}+\tilde{\alpha}_{2} w_{2}, \quad \frac{\mathrm{~d} w_{2}}{\mathrm{~d} t}=-\tilde{\alpha}_{2} w_{1}+\tilde{\alpha}_{1} w_{2}, \quad \frac{\mathrm{~d} w_{3}}{\mathrm{~d} t}=\tilde{\beta}_{1} w_{1}+\tilde{\beta}_{2} w_{2} \tag{82}
\end{equation*}
$$

we get

$$
\begin{gather*}
\frac{\mathrm{d} a_{1}}{\mathrm{~d} t}+a_{1} \alpha_{1}-a_{2} \alpha_{2}=a_{1} \tilde{\alpha}_{1}-a_{2} \tilde{\alpha}_{2}, \quad \frac{\mathrm{~d} a_{2}}{\mathrm{~d} t}+a_{2} \alpha_{1}+a_{1} \alpha_{2}=a_{2} \tilde{\alpha}_{1}+a_{1} \tilde{\alpha}_{2}  \tag{83}\\
\beta_{1}=a_{1} \tilde{\beta}_{1}-a_{2} \tilde{\beta}_{2}, \quad \beta_{2}=a_{2} \tilde{\beta}_{1}+a_{1} \tilde{\beta}_{2}
\end{gather*}
$$

Hence

$$
\begin{equation*}
\beta_{1}^{2}+\beta_{2}^{2}=\left(a_{1}^{2}+a_{2}^{2}\right)\left(\tilde{\beta}_{1}^{2}+\tilde{\beta}_{2}^{2}\right) \tag{84}
\end{equation*}
$$

and we have to distinguish two cases. In the first case

$$
\begin{equation*}
\beta_{1}=\beta_{2}=0 \tag{85}
\end{equation*}
$$

and $v(t)$ is situated in a fixed straight line; we have seen that this leads to a rotation. In the general case $\beta_{1}^{2}+\beta_{2}^{2} \neq 0$ and we may achieve

$$
\begin{equation*}
\beta_{1}=1, \quad \beta_{2}=0 . \tag{86}
\end{equation*}
$$

These conditions determine the frames $\left\{v_{i}(t)\right\}$ uniquely, and $\alpha_{1}(t), \alpha_{2}(t)$ are the invariants of our motion. Let us suppose (30) and

$$
\begin{gather*}
v_{1}(t)=a_{1} V_{1}+a_{2} V_{2}, \quad v_{2}(t)=-a_{2} V_{1}+a_{1} V_{2},  \tag{87}\\
v_{3}(t)=A C^{-1} \cdot V_{1}+B C^{-1} \cdot V_{2}+V_{3} .
\end{gather*}
$$

Then

$$
\begin{align*}
\frac{\mathrm{d} v_{1}}{\mathrm{~d} t}= & \left(a_{1}^{2}+a_{2}^{2}\right)^{-1}\left\{\left(a_{1} \frac{\mathrm{~d} a_{1}}{\mathrm{~d} t}+a_{2} \frac{\mathrm{~d} a_{2}}{\mathrm{~d} t}\right) v_{1}+\left(a_{1} \frac{\mathrm{~d} a_{2}}{\mathrm{~d} t}-a_{2} \frac{\mathrm{~d} a_{1}}{\mathrm{~d} t}\right) v_{2}\right\}  \tag{88}\\
\frac{\mathrm{d} v_{2}}{\mathrm{~d} t}= & \left(a_{1}^{2}+a_{2}^{2}\right)^{-1}\left\{\left(a_{2} \frac{\mathrm{~d} a_{1}}{\mathrm{~d} t}-a_{1} \frac{\mathrm{~d} a_{2}}{\mathrm{~d} t}\right) v_{1}+\left(a_{1} \frac{\mathrm{~d} a_{1}}{\mathrm{~d} t}+a_{2} \frac{\mathrm{~d} a_{2}}{\mathrm{~d} t}\right) v_{2}\right\} \\
& \frac{\mathrm{d} v_{3}}{\mathrm{~d} t}=\left(a_{1}^{2}+a_{2}^{2}\right)^{-1}\left\{a_{1} \frac{\mathrm{~d}\left(A C^{-1}\right)}{\mathrm{d} t}+a_{2} \frac{\mathrm{~d}\left(B C^{-1}\right)}{\mathrm{d} t}\right\} v_{1}+ \\
& +\left(a_{1}^{2}+a_{2}^{2}\right)^{-1}\left\{-a_{2} \frac{\mathrm{~d}\left(A C^{-1}\right)}{\mathrm{d} t}+a_{1} \frac{\mathrm{~d}\left(B C^{-1}\right)}{\mathrm{d} t}\right\} v_{2}
\end{align*}
$$

In the general case

$$
\begin{equation*}
\left(\frac{\mathrm{d}\left(A C^{-1}\right)}{\mathrm{d} t}\right)^{2}+\left(\frac{\mathrm{d}\left(B C^{-1}\right)}{\mathrm{d} t}\right)^{2} \neq 0 ; \tag{89}
\end{equation*}
$$

of course, we are going to study just this case. The conditions (86) determine $a_{1}, a_{2}$ and it is easy to see that the invariants of our motion are given by

$$
\begin{gather*}
\alpha_{1}=\frac{\mathrm{d}}{\mathrm{~d} t} \log \left\{\left(\frac{\mathrm{~d}\left(A C^{-1}\right)}{\mathrm{d} t}\right)^{2}+\left(\frac{\mathrm{d}\left(B C^{-1}\right)}{\mathrm{d} t}\right)^{2}\right\}^{1 / 2}  \tag{90}\\
\alpha_{2}=\left\{\left(\frac{\mathrm{d}\left(A C^{-1}\right)}{\mathrm{d} t}\right)^{2}+\left(\frac{\mathrm{d}\left(B C^{-1}\right)}{\mathrm{d} t}\right)^{2}\right\}^{-1} \\
\cdot\left\{\frac{\mathrm{~d}\left(A C^{-1}\right)}{\mathrm{d} t} \cdot \frac{\mathrm{~d}^{2}\left(B C^{-1}\right)}{\mathrm{d} t^{2}}-\frac{\mathrm{d}\left(B C^{-1}\right)}{\mathrm{d} t} \cdot \frac{\mathrm{~d}^{2}\left(A C^{-1}\right)}{\mathrm{d} t^{2}}\right\}
\end{gather*}
$$

Let the canonical parameter be, as above, introduced by the condition $v_{3}(t)=v(t)$; we see that $\alpha+$ constant is the set of canonical parameters. Using (39), a simple calculation yields

$$
\begin{equation*}
\alpha_{1}=\frac{\mathrm{d}}{\mathrm{~d} \alpha} \log \left|\frac{\mathrm{~d} s}{\mathrm{~d} \alpha}\right|, \quad \alpha_{2}=\frac{1}{2} i\left|\frac{\mathrm{~d} s}{\mathrm{~d} \alpha}\right|^{-2}\left(\frac{\mathrm{~d} s}{\mathrm{~d} \alpha} \cdot \frac{\mathrm{~d}^{2} \bar{s}}{\mathrm{~d} \alpha^{2}}-\frac{\mathrm{d} \bar{s}}{\mathrm{~d} \alpha} \cdot \frac{\mathrm{~d}^{2} s}{\mathrm{~d} \alpha^{2}}\right) . \tag{91}
\end{equation*}
$$

Let us determine the motions with constant invariants. From (911) we have

$$
\begin{equation*}
\frac{\mathrm{d} s}{\mathrm{~d} \alpha} \cdot \frac{\mathrm{~d} \bar{s}}{\mathrm{~d} \alpha}=c_{1} e^{2 \alpha_{1} \alpha} ; \quad c_{1}>0 \tag{92}
\end{equation*}
$$

and

$$
\begin{equation*}
\frac{\mathrm{d} s}{\mathrm{~d} \alpha} \cdot \frac{\mathrm{~d}^{2} \bar{s}}{\mathrm{~d} \alpha^{2}}+\frac{\mathrm{d} \bar{s}}{\mathrm{~d} \alpha} \cdot \frac{\mathrm{~d}^{2} s}{\mathrm{~d} \alpha^{2}}=2 c_{1} \alpha_{1} e^{2 \alpha_{1} \alpha} . \tag{93}
\end{equation*}
$$

(912) implies

$$
\begin{equation*}
\frac{\mathrm{d} s}{\mathrm{~d} \alpha} \cdot \frac{\mathrm{~d}^{2} \bar{s}}{\mathrm{~d} \alpha^{2}}-\frac{\mathrm{d} \bar{s}}{\mathrm{~d} \alpha} \cdot \frac{\mathrm{~d}^{2} s}{\mathrm{~d} \alpha^{2}}=-2 i c_{1} \alpha_{2} e^{2 \alpha_{1} \alpha} \tag{94}
\end{equation*}
$$

and we get

$$
\begin{equation*}
\frac{\mathrm{d}^{2} s}{\mathrm{~d} \alpha^{2}}=\left(\alpha_{1}+i \alpha_{2}\right) \frac{\mathrm{d} s}{\mathrm{~d} \alpha}, \tag{95}
\end{equation*}
$$

i.e., in the case $\alpha_{1}^{2}+\alpha_{2}^{2} \neq 0$,

$$
\begin{equation*}
s=c_{2} e^{\left(\alpha_{1}+i \alpha_{2}\right) \alpha}+c_{3} ; \quad c_{2}, c_{3} \in \mathbb{C} ; \tag{96}
\end{equation*}
$$

of course,

$$
\begin{equation*}
c_{1}=\left|c_{2}\right|^{2}\left(\alpha_{1}^{2}+\alpha_{2}^{2}\right) . \tag{97}
\end{equation*}
$$

Thus we have to solve the equation

$$
\begin{equation*}
\frac{\mathrm{d} r}{\mathrm{~d} \alpha}+i r=c_{2} e^{\left(\alpha_{1}+i \alpha_{2}\right) \alpha}+c_{3} . \tag{98}
\end{equation*}
$$

Suppose

$$
\begin{equation*}
\alpha_{1}+i\left(\alpha_{2}+1\right) \neq 0 . \tag{99}
\end{equation*}
$$

The general solution of (98) is then

$$
\begin{equation*}
r=c_{2}\left(\alpha_{1}+i \alpha_{2}+i\right)^{-1} e^{\left(\alpha_{1}+i \alpha_{2}\right) \alpha}+c_{4} e^{-i \alpha}-i c_{3} ; \quad c_{4} \in \mathbb{C} . \tag{100}
\end{equation*}
$$

Our motion normalized by the condition $g(0)=$ identity is then

$$
\begin{equation*}
z^{*}=\left(z+c_{4}\right) e^{-i \alpha}+c_{2}\left(\alpha_{1}+i \alpha_{2}+i\right)^{-1}\left(e^{\left(\alpha_{1}+i \alpha_{2}\right) \alpha}-1\right)-c_{4} . \tag{101}
\end{equation*}
$$

In the case

$$
\begin{equation*}
\alpha_{1}=0, \quad \alpha_{2}=-1 \tag{102}
\end{equation*}
$$

the general solution of $(98)$ is

$$
\begin{equation*}
r=\left(c_{2} \alpha+c_{4}\right) e^{-i \alpha}-i c_{3} \tag{103}
\end{equation*}
$$

and the corresponding motion is

$$
\begin{equation*}
z^{*}=\left(z+c_{2} \alpha+c_{4}\right) e^{-i \alpha}-c_{4} . \tag{104}
\end{equation*}
$$

It remains to deal with the case $\alpha_{1}=\alpha_{2}=0$. Then

$$
\begin{equation*}
s=c_{2}^{\prime} \alpha+c_{3}^{\prime}, \quad c_{2}^{\prime}, c_{3}^{\prime} \in \mathbb{C} ; \tag{105}
\end{equation*}
$$

of course,

$$
\begin{equation*}
\left|c_{2}^{\prime}\right|^{2}=c_{1} . \tag{106}
\end{equation*}
$$

From (105),

$$
\begin{equation*}
r=c_{4}^{\prime} e^{-i \alpha}-i c_{2}^{\prime} \alpha+c_{2}^{\prime}-i c_{3}^{\prime} ; \quad c_{4}^{\prime} \in \mathbb{C} . \tag{107}
\end{equation*}
$$

The corresponding motion is then

$$
\begin{equation*}
z^{*}=\left(z+c_{4}^{\prime}\right) e^{-i \alpha}-i c_{2}^{\prime} \alpha-c_{4}^{\prime} . \tag{108}
\end{equation*}
$$

Theorem 2. The motions with constant invariants $\alpha_{1}, \alpha_{2}$ are given either by (101) or (104) or (108).

## Souhrn

## KINEMATIKA V EUKLIDOVĚ ROVINĚ

## El Said El Shinnawy

A. Karger [1] studoval kinematickou geometrii v homogenním prostoru, jehož grupy pohybů jsou jisté speciální Lieovy grupy. Předložený článck se omezuje na Euklidovu rovinu, ale podává metodu, vedoucí k řešení problému ekvivalence pro všechny Lieovy grupy pohybů. Kromě toho jsou uvedeny všechny transitivní jednoparametrické soustavy pohybů v $E^{2}$.

Author's address: Dr. El Said El Shinnawy, Department of Geometry, MTC, Cairo.
