## ON THE EXISTENCE OF A BOUNDED SOLUTION OF A NON-LINEAR DIFFERENTIAL EQUATION

M. Jakubičková, Bratislava

Received March 16, 1968
In this paper the existence of a solution of the differential equation

$$
\begin{equation*}
y^{\prime \prime}-y=f\left(x, y, y^{\prime}\right) \tag{1}
\end{equation*}
$$

which is bounded together with its first derivative on the whole real line, is proved under the condition that the function $f$ is continuous and bounded.

Let us consider first the existence of a bounded solution of the linear differential equation

$$
\begin{equation*}
y^{\prime \prime}-y=f(x) \tag{2}
\end{equation*}
$$

where $f(x) \in C^{\circ}(I), I=(-\infty, \infty)$ and $|f(x)| \leqq K$ on $I$. It is clear that this equation has at most one such solution. We are going to give the proof of the existence of a bounded solution of the equation (2) as follows. A hint of this proof was given in an exercise in the book [1], p. 297.

Homogeneous boundary-value problem

$$
y^{\prime \prime}-y=0, \quad x \in\langle-a, a\rangle
$$

$$
\begin{equation*}
y(-a)=y(a)=0 \tag{3}
\end{equation*}
$$

where $a>0$, has only a trivial solution. Therefore the inhomogeneous boundary-value problem (2), (3) has one and only one solution

$$
\begin{equation*}
y_{a}(x)=\int_{-a}^{a} G_{a}(x, t) f(t) \mathrm{d} t, \quad x \in\langle-a, a\rangle \tag{4}
\end{equation*}
$$

where

$$
G_{a}(x, t)=\left\{\begin{array}{l}
\frac{\left(-\mathrm{e}^{-2 a+t}+\mathrm{e}^{-t}\right)\left(-\mathrm{e}^{2 a+x}+\mathrm{e}^{-x}\right)}{2\left(\mathrm{e}^{2 a}-\mathrm{e}^{-2 a}\right)}-a \leqq x \leqq t  \tag{5}\\
\frac{\left(-\mathrm{e}^{2 a+t}+\mathrm{e}^{-t}\right)\left(-\mathrm{e}^{-2 a+x}+\mathrm{e}^{-x}\right)}{2\left(\mathrm{e}^{2 a}-\mathrm{e}^{-2 a}\right)} t \leqq x \leqq a
\end{array}\right.
$$

is the Green's function of the problem (2), (3). The solution $y_{a}(x)$ can be continued to the whole interval $I$. Further there exists

$$
\begin{equation*}
y(x)=\lim _{a \rightarrow \infty} y_{a}(x)=-\frac{1}{2} \int_{-\infty}^{\infty} \mathrm{e}^{-|x-t|} \cdot f(t) \mathrm{d} t \tag{6}
\end{equation*}
$$

where the convergence is uniform on every closed interval $\langle-b, b\rangle$, $b>0$. For $x \in\langle-b, b\rangle, a \geqq b$ the inequality

$$
\begin{aligned}
& \left|\int_{-a}^{a} G_{a}(x, t) f(t) \mathrm{d} t+\frac{1}{2} \int_{-\infty}^{\infty} \mathrm{e}^{-|x-t|} \cdot f(t) \mathrm{d} t\right| \leqq \mid \int_{-a}^{a} G_{a}(x, t) f(t) \mathrm{d} t+ \\
+ & \frac{1}{2} \int_{-a}^{a} \mathrm{e}^{-|x-t|} \cdot f(t) \mathrm{d} t\left|+\left|\frac{1}{2} \int_{-\infty}^{\infty} \mathrm{e}^{-|x-t|} \cdot f(t) \mathrm{d} t-\frac{1}{2} \int_{-a}^{a} \mathrm{e}^{-|x-t|} \cdot f(t) \mathrm{d} t\right|\right.
\end{aligned}
$$

is true. Assuming that $a \geqq 2 b>0$ we estimate first the first term on the right side of the inequality.

$$
\begin{gathered}
\left|\int_{-a}^{a} G_{a}(x, t) f(t) \mathrm{d} t+\frac{1}{2} \int_{-a}^{a} \mathrm{e}^{-|x-t|} \cdot f(t) \mathrm{d} t\right| \leqq \\
\leqq\left|\int_{-a}^{x} \frac{\left(-\mathrm{e}^{2 a+t}+\mathrm{e}^{-t}\right)\left(-\mathrm{e}^{-2 a+x}+\mathrm{e}^{-x}\right)}{2\left(\mathrm{e}^{2 a}-\mathrm{e}^{-2 a}\right)} f(t) \mathrm{d} t+\frac{1}{2} \int_{-a}^{x} \mathrm{e}^{t-x} \cdot f(t) \mathrm{d} t\right|+ \\
+\left|\int_{x}^{a} \frac{\left(-\mathrm{e}^{-2 a+t}+\mathrm{e}^{-t}\right)\left(-\mathrm{e}^{2 a+x}+\mathrm{e}^{-x}\right)}{2\left(\mathrm{e}^{2 a}-\mathrm{e}^{-2 a}\right)} f(t) \mathrm{d} t+\frac{1}{2} \int_{x}^{a} \mathrm{e}^{x-t} f(t) \mathrm{d} t\right| \leqq \\
\leqq \frac{K}{2\left(\mathrm{e}^{2 a}-\mathrm{e}^{-2 a}\right)}\left\{\int_{-a}^{x}\left|\mathrm{e}^{t+x}+\mathrm{e}^{-(t+x)}-\mathrm{e}^{-2 a}\left(\mathrm{e}^{t-x}+\mathrm{e}^{-(t-x)}\right)\right| \mathrm{d} t+\right. \\
\left.\left.+\int_{x}^{a} \mid \mathrm{e}^{t+x}+\mathrm{e}^{-(t+x)}-\mathrm{e}^{-2 a( } \mathrm{e}^{t-x}+\mathrm{e}^{-(t-x)}\right) \mid \mathrm{d} t\right\}= \\
=\frac{K}{2\left(\mathrm{e}^{2 a}-\mathrm{e}^{-2 a}\right)}\left(\mathrm{e}^{a}+\mathrm{e}^{-3 a}-2 \mathrm{e}^{-a}\right)\left(\mathrm{e}^{x}+\mathrm{e}^{-x}\right) \leqq \\
\leqq \frac{2 K \mathrm{e}^{b}}{2\left(\mathrm{e}^{2 a}-\mathrm{e}^{-2 a}\right)}\left(\mathrm{e}^{a}+\mathrm{e}^{-3 a}-2 \mathrm{e}^{-a}\right)= \\
=\frac{K \cdot \mathrm{e}^{b}}{\left(1-\mathrm{e}^{-4 a}\right)}\left(\mathrm{e}^{-a}+\mathrm{e}^{-5 a}-2 \mathrm{e}^{-3 a}\right)<\frac{\varepsilon}{2}
\end{gathered}
$$

for a sufficiently great $a$.
Similarly we get for a sufficiently great $a$, that for the second term the inequality

$$
\frac{1}{2}\left|\int_{-\infty}^{\infty} \mathrm{e}^{-|x-t|} \cdot f(t) \mathrm{d} t-\int_{-a}^{a} \mathrm{e}^{-|x-t|} \cdot f(t) \mathrm{d} t\right|<\frac{\varepsilon}{2}
$$

holds. Since (6) fulfils the conditions of the theorem on the differentiating of the parametric integral the following relation

$$
\begin{gather*}
y^{\prime}(x)=\frac{1}{2} \int_{-\infty}^{x} \mathrm{e}^{t-x} \cdot f(t) \mathrm{d} t-\frac{1}{2} \int_{x}^{\infty} \mathrm{e}^{-t+x} \cdot f(t) \mathrm{d} t=  \tag{7}\\
=\int_{-\infty}^{x} \mathrm{e}^{t-x} f(t) \mathrm{d} t+y(x)
\end{gather*}
$$

is true. Applying the same theorem to (7) we get
$y^{\prime \prime}(x)=-\frac{1}{2} \int_{-\infty}^{x} \mathrm{e}^{-x+t} \cdot f(t) \mathrm{d} t-\frac{1}{2} \int_{x}^{\infty} \mathrm{e}^{-t+x} \cdot f(t) \mathrm{d} t+f(x)=y(x)+f(x)$.
We see that (6) is a solution of the differential equation (2). This ends the proof of

Lemma: Let $f(x) \in C^{\circ}(-\infty, \infty)$ and $|f(x)| \leqq K, K>0, x \in(-\infty, \infty)$. Then there exists one and only one solution $y(x)$ of the equation (2) which is bounded together with its first derivative in $(-\infty, \infty)$. This solution is given by the formula

$$
y(x)=-\frac{1}{2} \int_{-\infty}^{\infty} \mathrm{e}^{-|x-t|} \cdot f(t) \mathrm{d} t
$$

and on each interval 〈-b,b〉 is a uniform limit for $a \rightarrow \infty$ of the solutions $y_{u}(x)$ of the boundary-value problem (2), (3).

Theorem: Let $f\left(x, y, y^{\prime}\right)$ be a continuous bounded function of $x, y$, $y^{\prime} \in(-\infty, \infty)$. Then there exists at least one solution of the equation (1) on the interval $(-\infty, \infty)$ which is bounded together with its first derivative in $(-\infty, \infty)$.

Proof: On the basis of the lemma the solution of the integro-differential equation

$$
\begin{equation*}
y(x)=-\frac{1}{2} \int_{-\infty}^{\infty} \mathrm{e}^{-|x-t|} \cdot f\left(t, y(t), y^{\prime}(t)\right) \mathrm{d} t \tag{8}
\end{equation*}
$$

will be a bounded solution of the equation (1) which has a bounded first derivative. The existence of the solution (8) we shall prove with the help of Tychonoff fixed point theorem.

Let $E=C^{1}(-\infty, \infty)$ be the space of functions on which a countable system of semi-norms

$$
p_{n}[y(x)]=\max \left[\max _{x \in\langle-n, n\rangle}|y(x)|, \max _{x \in\langle-n, n\rangle}\left|y^{\prime}(x)\right|\right], \quad n=1,2, \ldots
$$

is defined. By the family of these semi-norms $E$ is complete locally convex space. Let $M=\left\{y(x) \in E:|y(x)| \leqq K,\left|y^{\prime}(x)\right| \leqq 2 K, \quad x \in\right.$ $\in(-\infty, \infty)\}$, where the constant $K$ is such that $\left|f\left(x, y, y^{\prime}\right)\right| \leqq K$ for all $x, y, y^{\prime}$. The set $M$ is closed, convex and bounded. Let

$$
\begin{equation*}
T y(x)=-\frac{1}{2} \int_{-\infty}^{\infty} \mathrm{e}^{-|x-t|} \cdot f\left[t, y(t), y^{\prime}(t)\right] \mathrm{d} t \tag{9}
\end{equation*}
$$

be the operator defined on the set $M$. We shall prove that it is continuous and compact on the set $M$ and $T M \subset M$. Let $\varepsilon>0$ and the natural $n$

$$
n>\ln \frac{9 K}{\varepsilon}
$$

be arbitrary numbers. Then for the $y(x), y_{0}(x) \in M$ and $x \in\langle-n, n\rangle$ the inequalities
(11) $\left|T y(x)-T y_{0}(x)\right| \leqq \frac{1}{2}\left\{\int_{-\infty}^{-2 n} \mathrm{e}^{-x+t} \cdot\left|f\left[t, y(t), y^{\prime}(t)\right]-f\left[t, y_{0}(t), y_{0}^{\prime}(t)\right]\right| \mathrm{d} t+\right.$

$$
+\mathrm{e}^{-\left|x_{-} t\right|} \cdot \int_{-2 n}^{2 n}\left|f\left[t, y(t), y^{\prime}(t)\right]-f\left[t, y_{0}(t), y_{0}^{\prime}(t)\right]\right| \mathrm{d} t+
$$

$$
\left.+\int_{2 n}^{\infty} \mathrm{e}^{x-t} \cdot\left|f\left[t, y(t), y^{\prime}(t)\right]-f\left[t, y_{0}(t), y_{0}^{\prime}(t)\right]\right| \mathrm{d} t\right\} \leqq
$$

$$
\begin{gathered}
\leqq \frac{1}{2}\left\{2 K \int_{-\infty}^{-2 n} \mathrm{e}^{-x+t} \mathrm{~d} t+\frac{\varepsilon}{9} \int_{-2 n}^{2 n} \mathrm{e}^{-|x-t|} \cdot \mathrm{d} t+2 K \int_{2 n}^{\infty} \mathrm{e}^{x-t} \mathrm{~d} t\right\} \leqq \\
\leqq K \cdot \mathrm{e}^{-n}+\frac{\varepsilon}{9}+K \mathrm{e}^{-n}<\frac{\varepsilon}{3}
\end{gathered}
$$

hold if $p_{2 n}\left(y-y_{0}\right)<\delta$, where $\delta>0$ is sufficiently small. Using the relation (7) we get

$$
[T y(x)]^{\prime}=-\frac{1}{2} \int_{-\infty}^{\infty} \mathrm{e}^{-|x-t|} \cdot f\left[t, y(t), y^{\prime}(t)\right] \mathrm{d} t+\int_{-\infty}^{x} \mathrm{e}^{-x+t} \cdot f\left[t, y(t), y^{\prime}(t)\right] \mathrm{d} t
$$

Then under the assumption (10) and considering (11)

$$
\begin{equation*}
\left|[T y(x)]^{\prime}-\left[T y_{0}(x)\right]^{\prime}\right| \leqq \frac{\varepsilon}{3}+ \tag{12}
\end{equation*}
$$

$$
\begin{gathered}
+\int_{-\infty}^{x} \mathrm{e}^{-x+t}\left|f\left[t, y(t), y^{\prime}(t)\right]-f\left[t, y_{0}(t), y_{0}^{\prime}(t)\right]\right| \mathrm{d} t<\frac{\varepsilon}{3}+ \\
+\int_{--\infty}^{\infty} \mathrm{e}^{-|x-t|} \cdot\left|f\left[t, y(t), y^{\prime}(t)\right]-f\left[t, y_{0}(t), y_{0}^{\prime}(t)\right]\right| \mathrm{d} t<\frac{\varepsilon}{3}+\frac{2}{3} \varepsilon=\varepsilon .
\end{gathered}
$$

It follows from the relations (11) and (12)

$$
p_{n}\left[T y(x)-T y_{0}(x)\right]<\varepsilon, \quad \text { if } \quad p_{2 n}\left[y(x)-y_{0}(x)\right]<\delta
$$

and thus continuity of the operator (9) is proved.
The compactness of the operator (9) will be proved by the application of the Ascoli-Arzela theorem. It is therefore sufficient to show that $T y(x)$ are equi-bounded and equi-continuous on each of the intervals $\langle-n, n\rangle$.

Let $y(x) \in M$. Then

$$
\begin{gathered}
|T y(x)|=\left|-\frac{1}{2} \int_{-\infty}^{\infty} \mathrm{e}^{-|x-t|} \cdot f\left[t, y(t), y^{\prime}(t)\right] \mathrm{d} t\right| \leqq \frac{K}{2} \int_{-\infty}^{\infty} \mathrm{e}^{-|x-t|} \mathrm{d} t=K \\
\left|[T y(x)]^{\prime}\right| \leqq\left|\int_{-\infty}^{x} \mathrm{e}^{-x+t} \cdot f\left[t, y(t), y^{\prime}(t)\right] \mathrm{d} t\right|+K \leqq 2 K .
\end{gathered}
$$

Hence $T M \subset M$ and at the same time also the set $T M$ is equibounded.
The equi-continuity of the functions from $T M$ on the interval $\langle-n, n\rangle$ will be proved in the following way: Let $\varepsilon>0$ be an arbitrary number and let

$$
\left|x_{1}-x_{2}\right|<\frac{\varepsilon}{4 K}, \quad x_{1}<x_{2}, \quad x_{1}, x_{2} \in\langle-n, n\rangle .
$$

Then

$$
\begin{aligned}
& \left.\left|T y\left(x_{1}\right)-T y\left(x_{2}\right)\right|=\frac{1}{2} \right\rvert\,\left(\mathrm{e}^{-x_{1}}-\mathrm{e}^{-x_{2}}\right) \int_{-\infty}^{x_{1}} \mathrm{e}^{t} \cdot f\left[t, y(t), y^{\prime}(t)\right] \mathrm{d} t+ \\
&+\int_{x_{1}}^{x_{2}}\left(\mathrm{e}^{x_{1}-t}-\mathrm{e}^{-x_{2}+t}\right) \cdot f\left[t, y(t), y^{\prime}(t)\right] \mathrm{d} t+ \\
&+\left(\mathrm{e}^{x_{1}}-\mathrm{e}^{x_{2}}\right) \int_{x_{2}}^{\infty} \mathrm{e}^{-t} \cdot f\left[t, y(t), y^{\prime}(t)\right] \mathrm{d} t \mid \leqq
\end{aligned}
$$

$$
\begin{aligned}
& \leqq \frac{1}{2}\left[\mathrm{e}^{-x_{1}}\left|x_{1}-x_{2}\right| K \int_{-\infty}^{x_{1}} \mathrm{e}^{t} \mathrm{~d} t+K \int_{x_{1}}^{x_{2}}\left(\mathrm{e}^{x_{1}-t}+\mathrm{e}^{-x_{2}+t}\right) \mathrm{d} t+\right. \\
& \left.+\mathrm{e}^{x_{2}}\left|x_{1}-x_{2}\right| \int_{x_{2}}^{\infty} \mathrm{e}^{-t} \mathrm{~d} t\right] \leqq \frac{1}{2}\left(K\left|x_{1}-x_{2}\right|+2 K\left|x_{1}-x_{2}\right|+\right. \\
& \left.+K\left|x_{1}-x_{2}\right|\right)=2 K\left|x_{1}-x_{2}\right|<\frac{\varepsilon}{2}, \\
& \begin{aligned}
\left|\left[T y\left(x_{1}\right)\right]^{\prime}-\left[T y\left(x_{2}\right)\right]^{\prime}\right| & \leqq \frac{1}{2}\left|\int_{-\infty}^{\infty}\left(\mathrm{e}^{-\left|x_{1}-t\right|}-\mathrm{e}^{-\left|x_{2}-t\right|}\right) \cdot f\left[t, y(t), y^{\prime}(t)\right] \mathrm{d} t\right|+ \\
& +\left|\int_{-\infty}^{x_{1}}\left(\mathrm{e}^{-x_{1}+t}-\mathrm{e}^{-x_{2}+t}\right) \cdot f\left[t, y(t), y^{\prime}(t)\right] \mathrm{d} t\right|+ \\
& \quad+\left|\int_{x_{1}}^{x_{2}} \mathrm{e}^{-x_{2}+t} \cdot f\left[t, y(t), y^{\prime}(t)\right] \mathrm{d} t\right| \leqq \\
\leqq 2 K\left|x_{1}-x_{2}\right| & +K\left|x_{1}-x_{2}\right|+K\left|x_{1}-x_{2}\right|=4 K\left|x_{1}-x_{2}\right|<\varepsilon
\end{aligned}
\end{aligned}
$$

what ends the proof of the equi-continuity of $T M$. It follows from what was proved that all assumptions of the Tychonoff fixed point theorem are fulfilled, so that there exists a fixed point of the operator (9) on $M$, which means that there exists at least one solution of the equation (1) which is bounded together with the first derivative on the whole real axis.
