# SIGNED 2-DOMINATION IN CATERPILLARS 

Bohdan Zelinka, Liberec
(Received December 19, 2003)

Abstract. A caterpillar is a tree with the property that after deleting all its vertices of degree 1 a simple path is obtained. The signed 2-domination number $\gamma_{\mathrm{s}}^{2}(G)$ and the signed total 2-domination number $\gamma_{\mathrm{st}}^{2}(G)$ of a graph $G$ are variants of the signed domination number $\gamma_{\mathrm{s}}(G)$ and the signed total domination number $\gamma_{\mathrm{st}}(G)$. Their values for caterpillars are studied.

Keywords: caterpillar, signed 2-domination number, signed total 2-domination number

MSC 2000: 05C69, 05C05

This paper concerns caterpillars. A caterpillar [1] is a tree with the property that after deleting all its vertices of degree 1 a simple path is obtained. According to this definition a caterpillar has at least three vertices. But we need not care about graphs with one or two vertices. For such graphs our considerations are trivial.

Let $G$ be a caterpillar. The mentioned simple path will be denoted by $B$ and called the body of the caterpillar $G$. Let the number of vertices of $B$ be $m$. Let $a_{1}, \ldots, a_{m}$ be these vertices and let $a_{i} a_{i+1}$ for $i=1, \ldots, m-1$ be the edges of $B$. By $[m]$ we shall denote the set of integers $i$ such that $1 \leqslant i \leqslant m$. For each $i \in[m]$ let $s_{i}$ be the degree of $a_{i}$ in $G$. The vector $\vec{s}=\left(s_{1}, \ldots, s_{m}\right)$ will be called the degree vector of the caterpillar $G$.

Now we shall define variants of the signed domination number and of the signed total domination number [2] of a graph. For a vertex $u \in V(G)$ the symbol $N(u)$ denotes the open neighbourhood of $u$ in $G$, i.e. the set of all vertices which are adjacent to $u$ in $G$. The closed neighbourhood of $u$ is $N[u]=N(u) \cup\{u\}$. Similarly the open 2-neighbourhood $N^{2}(u)$ is the set of all vertices having the distance 2 from $u$ in $G$. The closed 2-neighbourhood of $u$ is $N^{2}[u]=N[u] \cup N^{2}(u)$. If $f$ is a mapping
of $V(G)$ into some set of numbers and $S \subseteq V(G)$, then $f(S)=\sum_{x \in s} f(x)$ and the weight of $f$ is $w(f)=f(V(G))=\sum_{x \in V(G)} f(x)$.

Let $f: V(G) \rightarrow\{-1,1\}$. If $f\left(N^{2}[u]\right) \geqslant 1\left(\right.$ or $\left.f\left(N^{2}(u)\right) \geqslant 1\right)$ for each $u \in V(G)$, then $f$ is called a signed 2-dominating (or signed total 2-dominating, respectively) function on $G$. The minimum of weights $w(f)$ taken over all signed 2-dominating (or all signed total 2-dominating) functions $f$ is the signed 2-dominating number $\gamma_{\mathrm{s}}^{2}(G)$ (or the signed total 2-domination number $\gamma_{\mathrm{st}}^{2}(G)$, respectively) of $G$.

For each $i \in[m]$ let $t_{i} \in\{1,2\}$ and $t_{i} \equiv s_{i}+1(\bmod 2)$.
We shall prove a theorem concerning $\gamma_{\mathrm{s}}^{2}(G)$.
Theorem 1. Let $G$ be a caterpillar with the degree vector $\vec{s}=\left(s_{1}, \ldots, s_{m}\right)$ such that $n \geqslant 2$ and $s_{i} \geqslant 3$ for all $i \in[m]$. Then

$$
\gamma_{\mathbf{s}}^{2}(G)=\sum_{i=1}^{m} t_{i}-2 m+2
$$

Proof. Consider a vertex $a_{i}$ with $i \in[m]$. As $s_{i} \geqslant 3$, there exists at least one vertex $u \in N\left(a_{i}\right)$ which does not belong to $B$ and has degree 1 . Then $N^{2}[u]=N\left[a_{i}\right]$. Let $f$ be a signed 2-dominating function on $G$. Then $f\left(N^{2}[u]\right)=f\left(N\left[a_{i}\right]\right) \geqslant 1$. The set $N\left[a_{i}\right]$ has $s_{i}+1$ vertices. If $s_{i}$ is even, then $s_{i}+1$ is odd. At least $\frac{1}{2}\left(s_{i}+2\right)=\frac{1}{2} s_{i}+1$ vertices of $N\left[a_{i}\right]$ must have the value 1 in $f$ and at most $\frac{1}{2} s_{i}$ of them may have the value -1 . Then $f\left(N^{2}[u]\right) \geqslant\left(\frac{1}{2} s_{i}+1\right)-\frac{1}{2} s_{i}=1=t_{i}$. If $s_{i}$ is odd, then $s_{i+1}$ is even and at least $\frac{1}{2}\left(s_{i}+1\right)+1$ vertices of $N\left[a_{i}\right]$ must have the value 1 in $f$ and at most $\frac{1}{2}\left(s_{i}+1\right)-1$ of them may have the value -1 . Then $f\left(N^{2}[u]\right) \geqslant 2=t_{i}$. We may easily construct the function $f$ such that it has the value -1 in exactly $\frac{1}{2} s_{i}$ vertices of degree 1 in $N\left[a_{i}\right]$ with $i$ even and in exactly $\frac{1}{2}\left(s_{i}+1\right)-1=\frac{1}{2}\left(s_{i}-1\right)$ vertices of degree 1 in $N\left[a_{i}\right]$ with $i$ odd. In all other vertices (including all vertices of the body) the function $f$ has the value 1 .

We have $\bigcup_{i=1}^{m} N\left[a_{i}\right]=V(G)$. The vertex $a_{1}$ is contained in exactly two sets $N\left[a_{i}\right]$, namely in $N\left[a_{1}\right]$ and $N\left[a_{2}\right]$. Similarly $a_{m}$ is contained in exactly two sets $N\left[a_{m-1}\right]$, $N\left[a_{m}\right]$. For $i \in[m]-\{1, m\}$ the vertex $a_{i}$ is contained in exactly three sets $N\left[a_{i-1}\right]$, $N\left[a_{i}\right], N\left[a_{i+1}\right]$. Each vertex outside the body is contained in exactly one of these sets. By the Inclusion-Exclusion Principle we have

$$
\begin{aligned}
w(f) & =f(V(G))=\sum_{i=1}^{m} f\left(N\left[a_{i}\right]\right)-2 \sum_{i=2}^{m-1} f\left(a_{i}\right)-f\left(a_{1}\right)-f\left(a_{m}\right) \\
& =\sum_{i=1}^{m} t_{i}-2(m-2)-1-1=\sum_{i=1}^{m} t_{i}-2 m+2 .
\end{aligned}
$$

As $f$ is the minimum function satisfying the requirements, we have

$$
\gamma_{\mathrm{s}}^{2}(G)=w(f)=\sum_{i=1}^{m} t_{i}-2 m+2
$$

An analogous theorem concerns $\gamma_{\mathrm{st}}^{2}(G)$.
Theorem 2. Let $G$ be a caterpillar with the degree vector $\vec{s}=\left(s_{1}, \ldots, s_{m}\right)$ such that $m \geqslant 2$ and $s_{i} \geqslant 4$ for all $i \in[m]$. Then

$$
\gamma_{\mathrm{st}}^{2}(G)=\sum_{i=1}^{m} t_{i}+2
$$

Proof. Consider a vertex $a_{i}$ with $i \in[m]$. As $s_{i} \geqslant 5$, there exists at least one vertex $u \in N\left(a_{i}\right)$ which does not belong to $B$ and has degree 1 . Then $N^{2}(u)=$ $N\left(a_{i}\right)-\{u\}$. Let $f$ be a signed total 2-dominating function on $G$. Then $f\left(N^{2}(u)\right)=$ $f\left(N\left(a_{i}\right)-\{u\}\right) \geqslant 1$. The set $N\left(a_{i}\right)-\{u\}$ has $s_{i}-1$ vertices. If $s_{i}$ is even, then $s_{i}-1$ is odd. At least $\frac{1}{2} s_{i}$ vertices of $N\left(a_{i}\right)-\{u\}$ must have the value 1 in $f$ and at most $\frac{1}{2}\left(s_{i}-2\right)=\frac{1}{2} s_{i}-1$ of them may have the value -1 . Then $f\left(N^{2}(u)\right) \geqslant$ $\frac{1}{2} s_{i}-\left(\frac{1}{2} s_{i}-1\right)=1=t_{i}$. If $s_{i}$ is odd, then $s_{i}-1$ is even and at least $\frac{1}{2}\left(s_{i}-1\right)+1$ vertices of $N\left(a_{i}\right)-\{u\}$ must have the value 1 in $f$ and at most $\frac{1}{2}\left(s_{i}-1\right)-1$ of them may have the value -1 . Then $f\left(N^{2}(u)\right) \geqslant 2=t_{i}$. As $s_{i} \geqslant 5$ for $i \in[m]$, in both these cases we must admit the possibility $f(u)=1$. Then in the case of $s_{i}$ even we have $f\left(N\left(a_{i}\right)\right) \geqslant 2=t_{i}+1$ and in the case of $s_{i}$ odd we have $f\left(N\left(a_{i}\right)\right) \geqslant 3=t_{i}+1$. We may easily construct the function $f$ such that it has the value -1 in $\frac{1}{2} s_{i}-1$ vertices of degree 1 in $N\left(a_{i}\right)$ for $s_{i}$ even, in $\frac{1}{2}\left(s_{i}-1\right)-1=\frac{1}{2}\left(s_{i}-3\right)$ vertices of degree 1 in $S\left(a_{i}\right)$ for $s_{i}$ odd and the value 1 for all other vertices (including all vertices of $B)$. Each vertex $a_{j}$ for $j \in[m]-\{1, m\}$ is contained in two sets $N\left(a_{i}\right)$, namely in $N\left(a_{j-1}\right)$ and $N\left(a_{j+1}\right)$. Each other vertex is contained in exactly one set $N\left(a_{i}\right)$. Again by the Inclusion-Exclusion Principle we have

$$
\begin{aligned}
w(f) & =f(V(G))=\sum_{i=1}^{m} f\left(N\left(a_{i}\right)\right)-\sum_{i=2}^{m-1} f\left(a_{i}\right) \\
& =\sum_{i=1}^{m}\left(t_{i}+1\right)-(m-2)=\sum_{i=1}^{m} t_{i}+m-(m-2)=\sum_{i=1}^{m} t_{i}+2 .
\end{aligned}
$$

As $f$ is the minimum function satisfying the requirements, we have

$$
\gamma_{\mathrm{st}}^{2}(G)=w(f)=\sum_{i=1}^{m} t_{i}+2
$$

In Figs. 1 and 2 a caterpillar $G$ with the degree vector $(5,6,7)$ is depicted. We have $t_{1}=t_{3}=2, t_{2}=1$ and therefore $\gamma_{\mathrm{st}}^{2}(G)=7$ and $\gamma_{\mathrm{s}}^{2}(G)=1$. In Fig. 1 the values of the corresponding signed total 2-dominating function are illustrated; in the vertices denoted by + the value is 1 and in the vertices denoted by - it is -1 . Similarly in Fig. 2 the corresponding signed 2-dominating function is illustrated.

Fig. 1.

Fig. 2.

In Theorems 1 and 2 we had the assumption $m \geqslant 2$. The following proposition concerns the singular case $m=1$.

Proposition 1. Let $G$ be a caterpillar with the body consisting of one vertex, i.e. a star with the central vertex $a_{1}$ and with $s_{1} \geqslant 2$ vertices of degree 1. Then $\gamma_{\mathrm{st}}^{2}(G)$ is undefined and $\gamma_{\mathrm{s}}^{2}(G)=t_{1}$.

Proof. The open 2-neighbourhood $N^{2}\left(a_{1}\right)=\emptyset$ and thus $f\left(N^{2}\left(a_{1}\right)\right)=0$ for any function $f: V(G) \rightarrow\{-1,1\}$, hence none of such functions might be signed total 2-dominating in $G$. On the other hand, $N^{2}\left[a_{1}\right]=V(G)$ and $|V(G)|=s_{1}+1$. Analogously as in the proofs of Theorems 1 and 2 we prove that for $s_{1}$ even we have $\gamma_{\mathrm{s}}^{2}(G)=1=t_{1}$ and for $s_{1}$ odd we have $\gamma_{\mathrm{s}}^{2}(G)=2=t_{1}$.

Proposition 2. Let $G$ be a caterpillar with $m \equiv 2(\bmod 5), m \geqslant 5, s_{i}=3$ for all $i \in[m]$. Then $\gamma_{\mathrm{st}}^{2}(G) \leqslant \frac{4}{3}(m+3)+2$, while $\sum_{i=1}^{m} t_{i}+2=2(m+1)$.

Proof. As $s_{i}=3$ for each $i \in[m]$, we have $t_{i}=2$ for each $i \in[m]$. Each vertex $a_{i}$ for $i \in[m]-\{1, m\}$ is adjacent to exactly one vertex $v_{i}$ of degree 1 . The vertex $a_{1}$ is adjacent to two such vertices $v_{1}, w_{1}$ and similarly $a_{m}$ to $v_{m}, w_{m}$. Let $f: V(G) \rightarrow\{-1,1\}$ be defined so that $f\left(v_{i}\right)=-1$ for $i \equiv 0(\bmod 3)$ and $f(u)=1$ for all other vertices $u$. This is a signed total 2-dominating function on $G$ (this can be easily verified by the reader) and $w(f)=\frac{1}{3}(4 m+10)$. Therefore $\gamma_{\mathrm{st}}^{2}(G) \leqslant \frac{1}{3}(4 m+10)$, while $\sum_{i=1}^{m} t_{i}+2=2(m+1)$. For $m \geqslant 3$ we have $\frac{1}{3}(4 m+10)<2(m+1)$.

In Fig. 3 we see such a caterpillar for $m=8$ with the corresponding function $f$. In this case $\gamma_{\mathrm{st}}^{2}(G)=14, \sum_{i=1}^{m} t_{i}+2=18$. For the signed 2-domination number

Fig. 3.
here Theorem 1 holds. In Fig. 4 the same caterpillar is depicted with the function $f$ realizing the signed domination number $\gamma_{\mathrm{s}}^{2}(G)=\sum_{i=1}^{m} t_{i}-2 m+2=2$.

Fig. 4.

Proposition 3. Let $G$ be a caterpillar with $m \geqslant 2$ and $s_{i}=2$ for each $i \in[m]$. Then $\sum_{i=1}^{m} t_{i}-2 m+2<\gamma_{\mathrm{s}}^{2}(G)$, but $\sum_{i=1}^{m} t_{i}+2=\gamma_{\mathrm{st}}^{2}(G)$.

Proof. The caterpillar thus described is a simple path of length $m+1$. It has $m+2$ vertices. The inequality $\gamma_{\mathrm{s}}^{2}(G) \leqslant \sum_{i=1}^{m} t_{i}-2 m+2$ would imply that there exists a signed 2-dominating function $f$ which has the value -1 in $m$ vertices, while the value 1 only in two vertices. This is evidently impossible. On the other hand the open 2-neighbourhood of any vertex consists of at most two vertices and therefore the unique signed total 2-dominating function is the constant function equal to 1 in the whole set $V(G)$. Then

$$
\gamma_{\mathrm{st}}^{2}(G)=w(f)=\sum_{i=1}^{m} t_{i}+2=m+2
$$

Now we shall study the signed 2-domination number of a simple path $P_{n}$ with $n$ vertices (i.e. of length $n-1$ ). We shall not use the notation for caterpillars used above, but we shall denoted the vertices by $u_{1}, \ldots, u_{n}$ and edges by $u_{i} u_{i+1}$ for $i=$ $1, \ldots, n-1$.

Theorem 3. Let $P_{n}$ be a path with $n$ vertices. If $n \equiv 0(\bmod 5)$, then $\gamma_{\mathrm{s}}^{2}\left(P_{n}\right)=$ $\frac{1}{5} n$. In general, asymptotically $\gamma_{\mathrm{s}}^{2}\left(P_{n}\right) \approx\left\lfloor\frac{1}{5} n\right\rfloor$.

Proof. If $n \equiv 0(\bmod 5)$, then the closed neighbourhood $N^{2}\left[u_{i}\right]=\left\{u_{i-2}, u_{i-1}\right.$, $\left.u_{i}, u_{i+1}, u_{i+2}\right\}$ for $i \equiv 3(\bmod 5), 3 \leqslant i \leqslant n-2$, form a partition of $V\left(P_{n}\right)$. Let $f$
be a signed 2-dominating function on $P_{n}$. Then $f$ must have the value 1 in at least three vertices and may have the value -1 in at most two vertices of each class of this partition. Then $w(f) \geqslant \frac{3}{5} n=\frac{1}{5} n$. A function $f$ for which the equality occurs may be defined so that $f\left(u_{i}\right)=-1$ for $i \equiv 0(\bmod 5)$ and $i \equiv 1(\bmod 5)$ and $f\left(u_{1}\right)=1$ for $i \equiv 2(\bmod 5), i \equiv 3(\bmod 5)$ and $i \equiv 4(\bmod 5)$. Therefore $\gamma_{\mathrm{s}}^{2}\left(P_{n}\right)=w(f)=\frac{1}{5} n$.

Now let $m \equiv r(\bmod 5), r \leqslant 4$. Let $q=n-r$. We have $q \equiv 0(\bmod 5)$ and thus $\gamma_{\mathrm{s}}^{2}\left(P_{q}\right)=\frac{1}{5} q$. The path $P_{n}$ is obtained from $P_{q}$ by adding a path with $r$ vertices. Let $g$ be a minimum signed 2-dominating function on $P_{n}$, let $g_{0}$ be its restriction to $P_{q}$. We have $w\left(g_{0}\right)=\frac{1}{5} q$. Now the vertices of $P_{n}$ not in $P_{q}$ may have values 1 or -1 in $g$ and thus $\frac{1}{5} q-r \leqslant w(g) \leqslant \frac{1}{5} q+r$. In general, $\frac{1}{5} q-4 \leqslant \gamma_{\mathrm{s}}^{2}\left(P_{n}\right) \leqslant \frac{1}{5} q+4$. This implies

$$
\frac{9}{5 n}-\frac{4}{n} \leqslant \frac{\gamma_{\mathrm{s}}^{2}\left(P_{n}\right)}{n} \leqslant \frac{9}{5 n}+\frac{4}{n} .
$$

Therefore $\lim _{n \rightarrow \infty} \frac{\gamma_{s}^{2}\left(P_{n}\right)}{n}=\frac{9}{5 m}$ and thus $\gamma_{\mathrm{s}}^{2}\left(P_{n}\right) \approx \frac{9}{5}=\left\lfloor\frac{n}{5}\right\rfloor$.
In Fig. 5 we see a path $P_{15}$ (with $\gamma_{\mathrm{s}}^{2}\left(P_{15}\right)=3$ ) in which the corresponding signed 2-dominating function is illustrated.

Fig. 5.

As has already been mentioned, $\gamma_{\mathrm{st}}^{2}\left(P_{n}\right)=n$ for each positive integer $n$.
Without a proof we shall state the values of $\gamma_{\mathrm{s}}^{2}\left(P_{n}\right)$ for $n \leqslant 4$. We have $\gamma_{\mathrm{s}}^{2}\left(P_{1}\right)=1$, $\gamma_{\mathrm{s}}^{2}\left(P_{2}\right)=2, \gamma_{\mathrm{s}}^{2}\left(P_{3}\right)=1, \gamma_{\mathrm{s}}^{2}\left(P_{4}\right)=2$.
