# MULTISYMPLECTIC FORMS OF DEGREE THREE IN DIMENSION SEVEN 

JAROLÍM BUREŠ, JIŘí VANŽURA

#### Abstract

The group $G l(n)$ operates naturally on the space $\Lambda^{3} \mathbb{R}^{n *}$ of 3 -forms on $\mathbb{R}^{n}$. We say that two 3 -forms are of the same algebraic type if they belong to the same orbit. Multisymplectic 3 -structure on an $n$-dimensional manifold $M$ is given by a closed smooth 3 -form $\omega$ of maximal rank on $M$ which is of the same algebraic type at each point of $M$. This means that for each point $x \in M$ the form $\omega_{x}$ is isomorphic with a chosen canonical 3-form on $\mathbb{R}^{n}$. From the geometric point of view multisymplectic structure is a $G$-structure on $M$, where $G \subset G l(n)$ is the isotropy group at the canonical 3 -form. In the paper we use the classification of 3 -forms in dimension 7 (see [W], [D]), and we describe the isotropy groups of the individual canonical forms. The study of related geometric structures will be postponed to subsequent papers.

## 1. Algebraic properties of 3-forms on a real vector space

Let $V$ be an $n$-dimensional vector space over the field $\mathbb{R}$. The general linear group $G l(V)$ has natural action on $V$, and the induced natural actions on $V^{*}$ and on the spaces $\Lambda^{k} V, \Lambda^{k} V^{*}$ for any $k$.

$$
(\varphi \omega)(X)=\omega(\varphi X) \text { for every } \varphi \in G l(V), \omega \in \Lambda^{k} V^{*}, X \in \Lambda^{k} V
$$

We shall say that two $k$-forms are of the same algebraic type if they lie in the same orbit under the action of $G l(V)$. In every orbit we can choose a $k$-form which will be called canonical. Instead of the notation $\varphi \omega$ we shall use the more common notation $\varphi^{*} \omega$.

Let us consider now a 3 -form $\omega \in \Lambda^{3} V^{*}$. There is a set of invariants of the form $\omega$ under the induced action of $G l(n)$ on $\Lambda^{3} V^{*}$.

[^0]1. Rank of $\omega$, denoted by $\rho(\omega)$. It is defined as the minimal dimension of the subspaces $W \subset V^{*}$ such that $\omega \in \Lambda^{3} W$.
2. Irreducible length of $\omega$, denoted by $l(\omega)$. It is the minimal number of decomposable summands in all possible representations of $\omega$ (number of summands in the shortest representation of $\omega$ ).
3. The numbers $m(\omega)$ and $r(\omega)$ defined in the following way. Let $0 \neq w \in V$ and let $W$ be a complement of $[w]$ in $V$. Then for $\theta \in V^{*}$ satisfying $\theta(w)=1, \theta(W)=0$ we have a decomposition

$$
\Lambda^{3} V^{*}=\left(\theta \wedge \Lambda^{2} W^{*}\right) \oplus \Lambda^{3} W^{*}
$$

and for any $\omega \in \Lambda^{3} V^{*}$ there are uniquely defined elements $\gamma_{1} \in \Lambda^{2} W^{*}, \gamma_{2} \in \Lambda^{3} W^{*}$ with

$$
\omega=\theta \wedge \gamma_{1}+\gamma_{2}
$$

Let us denote by $D(\omega)$ the set of all $\gamma_{1}$ arising in this way, and similarly by $E(\omega)$ the set of all $\gamma_{2}$. We define

$$
\begin{aligned}
m(\omega) & =\min \left\{l\left(\gamma_{1}\right) ; \gamma_{1} \in D(\omega)\right\} \\
r(\varphi) & =\min \left\{l\left(\gamma_{2}\right) ; \gamma_{2} \in E(\omega)\right\} .
\end{aligned}
$$

The quadruple of numbers

$$
p(\omega)=(\rho(\varphi), l(\omega), m(\omega), r(\omega))
$$

enables to distinguish among the orbits of $G l(V)$ in $\Lambda^{3} V^{*}$. It is constant on each orbit, and to two different orbits correspond two different quadruples.

We are interested in 3 -forms of maximal rank on $V$, i. e. in the 3 -forms $\omega$ satisfying $\rho(\omega)=\operatorname{dim} V$. Such forms are usually called multisymplectic forms. It is well known that a form $\omega$ is multisymplectic if and only if the map

$$
V \rightarrow \Lambda^{2} V^{*}, \quad v \mapsto \iota(v) \omega=\omega(v, \cdot, \cdot)
$$

is injective.

1. Remark. For each dimension $n \leq 8$ there is only a finite number of types, for each dimension $n \geq 9$ there is always an infinite number of types. The first interesting nontrivial case appears for $n=6$, where the 3 -forms of maximal rank under the action of $G l(V)$ have three orbits. Two of them are open in $\Lambda^{3} V^{*}$, the third one has codimension 1. Open orbits exist also for $n=7$ and 8 . This fenomenon cannot occur if $=n \geq 9$. This can be easily deduced by comparing dimensions $n^{2}$ of $G l(V)$ and $\binom{n}{3}$ of $\Lambda^{3} V^{*}$. We shall restrict now to the case of dimension 7.

## 2. Classification of 3-forms of maximal rank 7

We fix a basis $e_{1}, \ldots, e_{7}$ of $V$ and we denote the dual basis of $V^{*}$ by $\alpha_{1}, \ldots, \alpha_{7}$.
2. Lemma. There is the following classification of 3-forms $\omega$ of maximal rank $\rho(\omega)=7$ in the 7 -dimensional space $V$ with respect to the action of the group $G l(V)$.

Type 1. $p\left(\omega_{1}\right)=(7,3,1,1)$. Representative of the orbit is

$$
\omega_{1}=\alpha_{1} \wedge \alpha_{2} \wedge \alpha_{7}+\alpha_{1} \wedge \alpha_{3} \wedge \alpha_{4}+\alpha_{2} \wedge \alpha_{5} \wedge \alpha_{6}
$$

Type 2. $p\left(\omega_{2}\right)=(7,3,1,2)$. Representative of the orbit is $\omega_{2}=\alpha_{1} \wedge \alpha_{2} \wedge \alpha_{5}+\alpha_{1} \wedge \alpha_{2} \wedge \alpha_{7}+\alpha_{1} \wedge \alpha_{4} \wedge \alpha_{7}-\alpha_{2} \wedge \alpha_{3} \wedge \alpha_{7}+\alpha_{3} \wedge \alpha_{4} \wedge \alpha_{6}+\alpha_{3} \wedge \alpha_{4} \wedge \alpha_{7}$.

Type 3. $p\left(\omega_{3}\right)=(7,3,1,0)$. Representative of the orbit is

$$
\omega_{3}=\alpha_{1} \wedge\left(\alpha_{2} \wedge \alpha_{7}-\alpha_{3} \wedge \alpha_{6}+\alpha_{4} \wedge \alpha_{5}\right)
$$

Type 4. $p\left(\omega_{4}\right)=(7,4,1,1)$. Representative of the orbit is

$$
\omega_{4}=\alpha_{1} \wedge\left(\alpha_{2} \wedge \alpha_{7}-\alpha_{3} \wedge \alpha_{6}+\alpha_{4} \wedge \alpha_{5}\right)+\alpha_{2} \wedge \alpha_{4} \wedge \alpha_{6}
$$

Type 5. $p\left(\omega_{5}\right)=(7,4,2,2)$. Representative of the orbit is

$$
\begin{gathered}
\omega_{5}=\alpha_{1} \wedge \alpha_{2} \wedge \alpha_{3}-\alpha_{1} \wedge \alpha_{4} \wedge \alpha_{5}+\alpha_{1} \wedge \alpha_{6} \wedge \alpha_{7} \\
+\alpha_{2} \wedge \alpha_{4} \wedge \alpha_{6}+\alpha_{2} \wedge \alpha_{5} \wedge \alpha_{7}+\alpha_{3} \wedge \alpha_{4} \wedge \alpha_{7}-\alpha_{3} \wedge \alpha_{5} \wedge \alpha_{6}
\end{gathered}
$$

Type 6. $p\left(\omega_{6}\right)=(7,4,1,2)$. Representative of the orbit is

$$
\omega_{6}=\alpha_{1} \wedge \alpha_{2} \wedge \alpha_{7}-\alpha_{1} \wedge \alpha_{3} \wedge \alpha_{6}+\alpha_{1} \wedge \alpha_{4} \wedge \alpha_{5}+\alpha_{2} \wedge \alpha_{3} \wedge \alpha_{5}+\alpha_{2} \wedge \alpha_{4} \wedge \alpha_{6}
$$

Type 7. $p\left(\omega_{7}\right)=(7,4,2,3)$. Representative of the orbit is $\omega_{7}=\alpha_{1} \wedge \alpha_{2} \wedge \alpha_{5}+\alpha_{1} \wedge \alpha_{3} \wedge \alpha_{6}+\alpha_{1} \wedge \alpha_{4} \wedge \alpha_{7}+\alpha_{2} \wedge \alpha_{3} \wedge \alpha_{7}-\alpha_{2} \wedge \alpha_{4} \wedge \alpha_{6}+\alpha_{3} \wedge \alpha_{4} \wedge \alpha_{5}$.

Type 8. $p\left(\omega_{8}\right)=(7,5,3,3)$. Representative of the orbit is

$$
\begin{gathered}
\omega_{8}=\alpha_{1} \wedge \alpha_{2} \wedge \alpha_{3}+\alpha_{1} \wedge \alpha_{4} \wedge \alpha_{5}-\alpha_{1} \wedge \alpha_{6} \wedge \alpha_{7}+\alpha_{2} \wedge \alpha_{4} \wedge \alpha_{6}+\alpha_{2} \wedge \alpha_{5} \wedge \alpha_{7} \\
+\alpha_{3} \wedge \alpha_{4} \wedge \alpha_{7}-\alpha_{3} \wedge \alpha_{5} \wedge \alpha_{6}
\end{gathered}
$$

3. Remark. Let $V^{C}$ be the complexification of $V$, and let $\omega^{C}$ denote the complexification of $\omega$. Then the following couples belong to the same orbit with respect to the action of the complex linear group $G l\left(V^{C}\right)$ :

$$
\omega_{1}^{C} \text { and } \omega_{6}^{C}, \quad \omega_{2}^{C} \text { and } \omega_{7}^{C}, \quad \omega_{5}^{C} \text { and } \omega_{8}^{C}
$$

## 3. Further invariants

We would like to find further invariants of the orbits of the forms $\omega_{i}, i=1, \ldots, 8$ with respect to the action of $G l(V)$. With any 3 -form $\omega$ we associate the subsets $\Delta^{k}(\omega) \subset V, k=2,3$

$$
\Delta^{k}(\omega)=\left\{v \in V ;(i(v) \omega)^{\wedge k}=0\right\}
$$

Instead of $\Delta^{k}\left(\omega_{j}\right)$ we shall use the notation $\Delta_{j}^{k}$. We introduce also a symmetric bilinear form on $V$ with values in $\Lambda^{7} V^{*}$

$$
b(v, w)=\iota(v) \omega \wedge \iota(w) \omega \wedge \omega
$$

This means that $b$ determines a conformal class of scalar bilinear forms, and simultaneously the corresponding conformal class of quadratic forms. A representative of the first class we shall denote by $B$, and the corresponding representative of the second class we denote by $Q$. As an invariant of a conformal class of bilinear forms we get the common kernel of its elements.

For a 3 -form $\omega$ we introduce its group of automorphisms

$$
O(\omega)=\left\{\varphi \in \operatorname{Aut}(V) ; \varphi^{*} \omega=\omega\right\} .
$$

It is obvious that $O(\omega)$ is the isotropy group of the action of $G l(V)$ on $\Lambda^{3} V^{*}$ at the point $\omega$. Instead of $O\left(\omega_{i}\right)$ we write $O_{i}$. One of the main aims of this paper is the determination of these groups.

## 4. FURTHER STUDY Of types.

Let us start to study further properties of the individual types from the above list of forms. If $v, w \in V$ we write $v=c_{1} e_{1}+\cdots+c_{7} e_{7}, w=d_{1} e_{1}+\cdots+d_{7} e_{7}$.

## Type 1. The form $\omega_{1}$.

We have

$$
\Delta_{1}^{2}=V_{3}^{a} \cup V_{3}^{b}, \quad \Delta_{1}^{3}=V_{6}^{a} \cup V_{6}^{b}
$$

where

$$
V_{3}^{a}=\left[e_{3}, e_{4}, e_{7}\right], \quad V_{3}^{b}=\left[e_{5}, e_{6}, e_{7}\right]
$$

and

$$
V_{6}^{a}=\left[e_{1}, e_{3}, e_{4}, e_{5}, e_{6}, e_{7}\right], \quad V_{6}^{b}=\left[e_{2}, e_{3}, e_{4}, e_{5}, e_{6}, e_{7}\right] .
$$

Further invariant subspaces of $V$ are $V_{1}=V_{3}^{a} \cap V_{3}^{b}, V_{5}=V_{6}^{a} \cap V_{6}^{b}$. Moreover, we have the quotients

$$
W_{2}=V / V_{5}, W_{4}^{a}=V / V_{3}^{a}, W_{4}^{b}=V / V_{3}^{b}, W_{6}=V / V_{1}
$$

and

$$
\begin{gathered}
Z_{1}^{a}=V_{6}^{a} / V_{5}, Z_{1}^{b}=V_{6}^{b} / V_{5}, Z_{2}^{a}=V_{3}^{a} / V_{1}, Z_{2}^{b}=V_{3}^{b} / V_{1}, \\
\tilde{Z_{2}^{a}}=V_{5} / V_{3}^{b}, \tilde{Z_{2}^{b}}=V_{5} / V_{3}^{a}, Z_{4}=V_{5} / V_{1} .
\end{gathered}
$$

We have obviously $W_{2}=Z_{1}^{a} \oplus Z_{1}^{b}$ and $Z_{4}=Z_{2}^{a} \oplus Z_{2}^{b}$. We get also

$$
\left(\iota(v) \omega_{1}\right) \wedge\left(\iota(w) \omega_{1}\right) \wedge \omega_{1}=3\left(c_{1} d_{2}+c_{2} d_{1}\right) \alpha_{1} \wedge \cdots \wedge \alpha_{7}
$$

The scalar form $B(v, w)=c_{1} d_{2}+c_{2} d_{1}$ induces a regular form of signature $(1,1)$ on $W_{2}$. We denote it by $B_{2}$. In fact, we obtain on $W_{2}$ a conformal structure of signature $(1,1)$.

Obviously, for every $\varphi \in O_{1}$ we have either $\varphi V_{3}^{a}=V_{3}^{a}$ and $\varphi V_{3}^{b}=V_{3}^{b}$ or $\varphi V_{3}^{a}=$ $V_{3}=b$ and $\varphi V_{3}^{b}=V_{3}^{a}$. We define a homomorphism

$$
\operatorname{sg}: O_{1} \rightarrow \mathbb{Z}_{2}
$$

in the following way

$$
\begin{array}{ll}
\operatorname{sg} \varphi=1 & \text { if } \varphi V_{3}^{a}=V_{3}^{a} \text { and } \varphi V_{3}^{b}=V_{3}^{b} \\
\operatorname{sg} \varphi=-1 & \text { if } \varphi V_{3}^{a}=V_{3}^{b} \text { and } \varphi V_{3}^{b}=V_{3}^{a}
\end{array}
$$

We obtain easily a split short exact sequence

$$
0 \rightarrow O_{1}^{+} \rightarrow O_{1} \xrightarrow{\text { sg }} \mathbb{Z}_{2} \rightarrow 0
$$

where $O_{1}^{+}=$kersg.
It is also obvious that every automorphism $\varphi \in O_{1}$ induces an automorphism $\tilde{\varphi} \in G L\left(Z_{4}\right)$, and that $\tilde{\varphi}\left(Z_{2}^{a} \oplus Z_{2}^{b}\right)=Z_{2}^{a} \oplus Z_{2}^{b}$. We can easily prove that

$$
\begin{aligned}
& \tilde{\varphi} Z_{2}^{a}=Z_{2}^{a} \text { and } \tilde{\varphi} Z_{2}^{b}=Z_{2}^{b} \text { iff } \operatorname{sg} \varphi=1 \\
& \tilde{\varphi} Z_{2}^{a}=Z_{2}^{b} \text { and } \tilde{\varphi} Z_{2}^{b}=Z_{2}^{a} \text { iff } \operatorname{sg} \varphi=-1
\end{aligned}
$$

This means that we can define a homomorphism

$$
\nu: O_{1}^{+} \rightarrow G L\left(Z_{2}^{a}\right) \oplus G L\left(Z_{2}^{b}\right), \quad \nu \varphi=\tilde{\varphi}
$$

It can be proved that this homomorphism is an epimorphism, and we obtain a split short exact sequence

$$
0 \rightarrow K \rightarrow O_{1}^{+}\left(\omega_{1}\right) \xrightarrow{\nu} G L\left(Z_{2}^{a}\right) \oplus G L\left(Z_{2}^{b}\right) \rightarrow 0
$$

where $K=\operatorname{ker} \nu$.
It is not difficult to see that the mapping $v \mapsto\left(\iota(v) \omega_{1}\right) \mid V_{5}$ induces a homomorphism $W_{2} \rightarrow \Lambda^{2} Z_{4}^{*}$. The image of this homomorphism is the subspace $\Lambda^{2} Z_{2}^{a *} \oplus \Lambda^{2} Z_{2}^{b *}$. Consequently, we get an isomorphism

$$
\kappa: W_{2} \rightarrow \Lambda^{2} Z_{2}^{a *} \oplus \Lambda^{2} Z_{2}^{b *}
$$

with $\kappa Z_{1}^{a}=\Lambda^{2} Z_{2}^{a *}$ and $\kappa Z_{1}^{b}=\Lambda^{2} Z_{2}^{b *}$.

Similarly, the mapping $v \mapsto \iota(v) \omega_{1}$ induces an isomorphism

$$
\lambda: V_{1} \rightarrow \Lambda^{2} W_{2}^{*}
$$

Let us consider again $\varphi \in O_{1}^{+}$. We denote $\hat{\varphi}$ the automorphism induced on $W_{2}$ by $\varphi$. An easy computation shows that

$$
\kappa(\hat{\varphi} w)=\frac{1}{\operatorname{det} \tilde{\varphi}} \kappa w, \quad \text { for every } w \in W_{2}
$$

This formula implies that

$$
\hat{\varphi} Z_{1}^{a}=Z_{1}^{a}, \quad \hat{\varphi} Z_{1}^{b}=Z_{1}^{b}
$$

Similar result we get for the isomorphism $\lambda$.

$$
\lambda(\varphi v)=\frac{1}{\operatorname{det} \hat{\varphi}} \lambda v \quad \text { for every } v \in V_{1}
$$

We are now going to investigate the subgroup $K$. It is obvious that an element $\varphi \in K$ has the form

$$
\begin{array}{lrr}
\varphi e_{1}=\varphi_{11} e_{1}+\varphi_{12} e_{2}+\varphi_{13} e_{3}+\varphi_{14} e_{4}+\varphi_{15} e_{5}+\varphi_{16} e_{6}+\varphi_{17} e_{7} \\
\varphi e_{2}=\varphi_{21} e_{1}+\varphi_{22} e_{2}+\varphi_{23} e_{3}+\varphi_{24} e_{4}+\varphi_{25} e_{5}+\varphi_{26} e_{6}+\varphi_{27} e_{7} \\
\varphi e_{3}= & e_{3} & \\
\varphi e_{4}= & & +\varphi_{37} e_{7} \\
\varphi e_{5}= & & +\varphi_{47} e_{7} \\
\varphi e_{6}= & & +e_{57} e_{7} \\
\varphi e_{7}= & & \\
\hline
\end{array}
$$

and the previous considerations show that

$$
\varphi_{11}=1, \varphi_{12}=0, \varphi_{21}=0, \varphi_{22}=1, \varphi_{77}=1
$$

Considering the equality $\varphi^{*} \omega_{1}=\omega_{1}$, we find that an automorphism $\varphi$ of the above form belongs to $O_{1}$ if and only if

$$
\varphi_{37}=\varphi_{24}, \quad \varphi_{47}=-\varphi_{23}, \quad \varphi_{57}=-\varphi_{16}, \quad \varphi_{67}=\varphi_{15}
$$

Let us consider a mapping

$$
\nu_{1}: K \rightarrow \tilde{Z}_{2}^{a}, \quad \nu_{1}(\varphi)=\left[(\varphi-i d) e_{1}\right]
$$

where [ ] denotes the class of the corresponding element from $V_{5}$ in the quotient $\tilde{Z}_{2}^{a}$. Similarly we define a mapping

$$
\nu_{2}: K \rightarrow \tilde{Z}_{2}^{b}, \quad \nu_{2}(\varphi)=\left[(\varphi-i d) e_{2}\right]
$$

Considering now $\tilde{Z}_{2}^{a}$ and $\tilde{Z}_{2}^{b}$ as commutative groups with the addition inherited from the vector space structures, we find easily that

$$
\nu_{1} \oplus \nu_{2}: K \rightarrow \tilde{Z}_{2}^{a} \oplus \tilde{Z}_{2}^{b}
$$

is a surjective homomorphism, i. e. an epimorphism. We get again a split short exact sequence

$$
0 \rightarrow L \rightarrow K \xrightarrow{\nu_{1} \oplus \nu_{2}} \tilde{Z}_{2}^{a} \oplus \tilde{Z}_{2}^{b} \cong \mathbb{R}^{4} \rightarrow 0,
$$

where $L$ denotes the kernel of $\nu_{1} \oplus \nu_{2}$. Finally, it is not difficult to find that $L=H \oplus H$, where $H$ is a Lie group diffeomorphic as a manifold with $\mathbb{R}^{3}$, and with a multiplication given by the formula

$$
\left(x_{1}, x_{2}, x_{3}\right)\left(y_{1}, y_{2}, y_{3}\right)=\left(x_{1}+y_{1}, x_{2}+y_{2}, x_{3}+y_{3}-x_{1} y_{2}+x_{2} y_{1}\right)
$$

In other words, $H$ is the Heisenberg group.
Summarizing, we obtain the following

## 4. Proposition.

$$
O_{1}=\left[\left((H \oplus H) \ltimes \mathbb{R}^{4}\right) \ltimes\left(G L\left(W_{2}^{a}\right) \oplus G L\left(W_{2}^{b}\right)\right)\right] \ltimes \mathbb{Z}_{2}
$$

with $\operatorname{dim} O_{1}=18$.
In the above formula $\ltimes$ denotes various semidirect products with respect to the splittings in the above split short exact sequences. For the sake of brevity we have omitted their description.

Type 2. The form $\omega_{2}$.
Here we have

$$
\begin{gathered}
\Delta_{2}^{2}=\left\{v \in V ; c_{1}=c_{2}=c_{3}=c_{4}=0, c_{5} c_{6}+c_{6} c_{7}+c_{7} c_{5}=0\right\} \\
\Delta_{2}^{3}=\left\{v \in V ; c_{1} c_{4}-c_{2} c_{3}=0\right\}
\end{gathered}
$$

and

$$
\left(\iota(v) \omega_{2}\right) \wedge\left(\iota(v) \omega_{2}\right) \wedge \omega_{2}=6\left(c_{1} d_{4}-c_{2} d_{3}-c_{3} d_{2}+c_{4} d_{1}\right) \alpha_{1} \wedge \cdots \wedge \alpha_{7}
$$

This means that we get a subspace $V_{3}=\left[e_{5}, e_{6}, e_{7}\right]$, and a quotient space $W_{4}=V / V_{3}$. On the subspace $V_{3}$ we shall consider the quadratic form

$$
Q_{3}(v)=c_{5} c_{6}+c_{6} c_{7}+c_{7} c_{5}
$$

which is of course determined only up to a multiple. The corresponding bilinear form we denote by $B_{3} . Q_{3}$ has signature ( 1,2 ). On $V$ we shall consider the quadratic form

$$
Q(v)=2\left(c_{1} c_{4}-c_{2} c_{3}\right)
$$

The corresponding bilinear form we denote by $B$. It is easy to see that the kernel of $B$ is the subspace $V_{3}$. The bilinear form $B$ induces on $W_{4}$ a regular bilinear form $B_{4}$. The corresponding quadratic form we denote by $Q_{4}$.

In $V_{3}$ we shall consider the orthonormal basis $f_{5}=e_{5}+e_{6}, f_{6}=e_{5}-e_{=} 6$, $f_{7}=e_{7}-e_{5}-e_{6}$ satisfying

$$
B_{3}\left(f_{5}, f_{5}\right)=1, \quad B_{3}\left(f_{6}, f_{6}\right)=-1, \quad B_{3}\left(f_{7}, f_{7}\right)=-1
$$

The mapping $v \mapsto \iota(v) \omega_{2}$ induces a monomorphism

$$
\lambda: V_{3} \rightarrow \Lambda^{2} W_{4}^{*}
$$

We denote $\sigma_{1}=\lambda\left(f_{5}\right), \sigma_{2}=\lambda\left(f_{6}\right), \sigma_{3}=\lambda\left(f_{7}\right)$. An easy computation shows that there are uniquely determined endomorphisms $E, F, G \in \operatorname{End}\left(W_{4}\right)$ such that

$$
\begin{aligned}
& \sigma_{1}\left(w_{1}, w_{2}\right)=B_{4}\left(E w_{1}, w_{2}\right), \\
& \sigma_{2}\left(w_{1}, w_{2}\right)=B_{4}\left(F w_{1}, w_{2}\right), \\
& \sigma_{3}\left(w_{1}, w_{2}\right)=B_{4}\left(G w_{1}, w_{2}\right)
\end{aligned}
$$

These endomorphisms satisfy the relations

$$
\begin{gathered}
E^{2}=-I, \quad F^{2}=I, \quad G^{2}=I \\
E F=-F E=G, \quad F G=-G F=-E, \quad G E=-E G=F,
\end{gathered}
$$

which shows that the associative subalgebra of $\operatorname{End}\left(W_{4}\right)$ generated by $I, E, F$, and $G$ is isomorphic to the algebra $\tilde{\mathbb{H}}$ of pseudoquaternions. Obviously, $W_{4}$ is an 1-dimensional free $\tilde{H}$-module.

We now start to investigate the group $O_{2}$ of automorphisms of the form $\omega_{2}$. Any element $\varphi \in O_{2}$ preserves the subspace $V_{3}$, and preserves up to a positive multiple the quadratic form $Q_{3}$. Therefore we can define the restriction homomorphisms

$$
\rho: O_{2} \rightarrow C O\left(Q_{3}\right), \quad \rho \varphi=\bar{\varphi}=\varphi \mid V_{3}
$$

where

$$
C O\left(Q_{3}\right)=\left\{\psi \in G L\left(V_{3}\right) ; \exists c>0 \text { such that } Q_{3}(\psi v)=c Q_{3}(v) \text { for all } v \in V_{3}\right\}
$$

Similarly $\varphi \in O_{2}$ induces an automorphism $\tilde{\varphi}$ of $W_{4}$. It must preserve the form $B_{4}$ up to a non-zero multiple (we remind that $B_{4}$ has signature ( 2,2 ). Consequently, we can define a homomorphism

$$
\mu: O_{2} \rightarrow C O\left(Q_{4}\right)
$$

where

$$
C O\left(Q_{4}\right)=\left\{\chi \in G L\left(W_{4}\right) ; \exists d \neq 0 \text { such that } Q_{4}(\chi w)=d Q_{4}(w) \text { for all } w \in W_{4}\right\}
$$

Considering the homomorphism $\operatorname{det} \rho: O_{2} \rightarrow \mathbb{R}^{*}$, we find that this homomorphism is an epimorphism. Consequently, we obtain a split short exact sequence

$$
0 \rightarrow O_{2}^{+} \rightarrow O_{2} \xrightarrow{\text { det } \rho} \mathbb{R}^{*} \rightarrow 0
$$

where $O_{2}^{+}=\operatorname{ker} \operatorname{det} \rho$.
Having in mind the short exact sequence

$$
0 \rightarrow S O(1,2) \rightarrow C O(1,2) \xrightarrow{\text { det }} \mathbb{R}^{*} \rightarrow 0
$$

we find easily a split short exact sequence

$$
0 \rightarrow K \rightarrow O_{2}^{+} \xrightarrow{\rho} S O\left(Q_{3}\right) \rightarrow 0
$$

where we write simply $\rho$ instead of $\rho \mid O_{2}^{+}$, and $K=\operatorname{ker} \rho$.
Next, we consider the restriction $\mu: K \rightarrow C O\left(Q_{4}\right)$ of the homomorphism $\mu$ to the subgroup $K$. It can be shown, that the image of $\mu$ consists precisely of automorphisms of the 1-dimensional $\tilde{\mathbb{H}}$-module $W_{4}$ preserving the bilinear form $B_{4}$. It is easy to see that this image can be identified with the group

$$
\tilde{S}^{3}=\{A \in \tilde{\mathbb{H}} ;(A, A)=1\}
$$

where $(\cdot, \cdot)$ denotes the standard product of pseudoquaternions. In this way we get a homomorphism $\mu: K \rightarrow \tilde{S}^{3}$, and standard considerations show that this homomorphism is an epimorphism. Consequently, we obtain a split short exact sequence

$$
0 \rightarrow L \rightarrow K \xrightarrow{\mu} \tilde{S}^{3} \rightarrow 0 .
$$

We shall introduce a subspace $V_{4}=\left[e_{1}, e_{2}, e_{3}, e_{4}\right]$. Obviously, there is a natural isomorphism of $V_{4}$ with $W_{4}$. Any element $\varphi \in L$ determines an endomorphism $D_{\varphi}: V \rightarrow V$ such that $D_{\varphi} V_{4} \subset V_{3}, D_{\varphi} \mid V_{3}=0$, and

$$
\begin{gathered}
\varphi e_{1}=e_{1}+D_{\varphi} e_{1}, \quad \varphi e_{2}=e_{2}+D_{\varphi} e_{2}, \quad \varphi e_{3}=e_{3}+D_{\varphi} e_{3}, \quad \varphi e_{4}=e_{4}+D_{\varphi} e_{4} \\
\varphi e_{5}=e_{5}, \quad \varphi e_{6}=e_{6}, \quad \varphi e_{7}=e_{7}
\end{gathered}
$$

It is obvious that the group

$$
\left\{i d+D ; D \in \operatorname{End}(V) \text { with } D V_{4} \subset V_{3} \text { and } D \mid V_{3}=0\right\}
$$

is commutative. This shows that also the group $L$ is commutative. Considering an automorphism $\varphi=i d+D$, we can easily see that

$$
\omega_{2}\left(\varphi e_{i}, \varphi e_{j}, \varphi e_{k}\right)=\omega_{2}\left(e_{i}, e_{j}, e_{k}\right) \quad \text { if }\{i, j, k\} \cap\{5,6,7\} \neq \emptyset
$$

This means that $\varphi=i d+D \in O_{2}$ if and only if

$$
\omega_{2}\left(\varphi e_{i}, \varphi e_{j}, \varphi e_{k}\right)=\omega_{2}\left(e_{i}, e_{j}, e_{k}\right)=0 \quad \text { for all } i, j, k \in\{1,2,3,4\}
$$

We can find easily that $\varphi=i d+D \in O_{2}$ if and only if the following four equations are satisfied.

$$
\begin{aligned}
& \omega_{2}\left(D e_{1}, e_{2}, e_{3}\right)+\omega_{2}\left(e_{1}, e_{2}, D e_{3}\right)=0 \\
& \omega_{2}\left(e_{1}, D e_{2}, e_{4}\right)+\omega_{2}\left(e_{1}, e_{2}, D e_{4}\right)=0 \\
& \omega_{2}\left(D e_{1}, e_{3}, e_{4}\right)+\omega_{2}\left(e_{1}, D e_{3}, e_{4}\right)=0 \\
& \omega_{2}\left(D e_{2}, e_{3}, e_{4}\right)+\omega_{2}\left(e_{2}, e_{3}, D e_{4}\right)=0
\end{aligned}
$$

Hence we can conclude that $L$ is a Lie group isomorphic with the Lie group $\mathbb{R}^{8}$. It is well known that $\tilde{S}^{3} \cong \operatorname{Spin}(1,2)$. We thus obtain

## 5. Proposition.

$$
O\left(\omega_{2}\right)=\left[\left(\mathbb{R}^{8} \ltimes \operatorname{Spin}(1,2)\right) \propto S O(1,2)\right] \ltimes \mathbb{R}^{*}
$$

with $\operatorname{dim} O_{2}=15$.
Again, we have not specified the splittings hidden in the above formula.

## Type 3. The form $\omega_{3}$.

Here we have

$$
\begin{gathered}
\Delta_{3}^{2}=\Delta_{3}^{3}=\left[e_{2}, e_{3}, e_{4}, e_{5}, e_{6}, e_{7}\right]=V_{6} \\
\left(\iota(v) \omega_{3}\right) \wedge\left(\iota(w) \omega_{3}\right) \wedge \omega_{3}=2 c_{1} d_{1} \alpha_{1} \wedge \cdots \wedge \alpha_{7}
\end{gathered}
$$

We denote also $W_{1}=V / V_{6}$. Because $\omega_{3} \mid V_{6}=0$, we find easily that the correspondence $v \in V \mapsto\left(\iota(v) \omega_{3}\right) \mid V_{6}$ induces a monomorphism

$$
\lambda: W_{1} \rightarrow \Lambda^{2} V_{6}^{*}
$$

We denote

$$
\sigma=\lambda e_{1}=\alpha_{2} \wedge \alpha_{7}-\alpha_{3} \wedge \alpha_{6}+\alpha_{4} \wedge \alpha_{5}
$$

This is obviously a symplectic form on the subspace $V_{6}$.
We start now to consider the group $O_{3}$ of automorphisms of the form $\omega_{3}$. Every element $\varphi \in O_{3}$ preserves the subspace $V_{6}$, and we denote $\bar{\varphi}=\varphi \mid V_{6}$. It can be proved that $\bar{\varphi}$ belongs to the conformal symplectic group $\operatorname{CSp}(\sigma) \cong \operatorname{CSp}(3, \mathbb{R})$. This means that we can introduce a restriction homomorphism $\rho: O_{3} \rightarrow \operatorname{CSp}(3, \mathbb{R})$. This homomorphism is an epimorphism, and we obtain a split short exact sequence

$$
0 \rightarrow K \rightarrow O_{3} \xrightarrow{\rho} C S p(3, \mathbb{R}) \rightarrow 0
$$

where $K=\operatorname{ker} \rho$. It is easy to verify that for every $\varphi \in K$ we have

$$
\begin{aligned}
\varphi e_{1} & =e_{1}+\varphi_{12} e_{2}+\cdots+\varphi_{17} e_{7} \\
\varphi e_{i} & =e_{i} \text { for } 2 \leq i \leq 7
\end{aligned}
$$

On the other hand every element of this form belongs to $K$. Moreover, we can immediately see that $K$ is isomorphic with $\mathbb{R}^{6}$ considered as a Lie group. Therefore we have

## 6. Proposition.

$$
O_{3}=\mathbb{R}^{6} \ltimes C S p(3, \mathbb{R})
$$

with $\operatorname{dim} O_{3}=28$.

Type 4. The form $\omega_{4}$.
For technical reasons this time we shall renumber our basis in $V$. We set

$$
f_{1}=e_{1}, \quad f_{2}=e_{2}, \quad f_{3}=e_{4}, \quad f_{4}=e_{6}, \quad f_{5}=e_{7}, \quad f_{6}=e_{5}, \quad f_{7}=e_{3}
$$

We denote $\beta_{1}, \ldots, \beta_{7}$ the dual basis to $f_{1}, \ldots, f_{7}$. With respect to this basis we have

$$
\omega_{4}=\beta_{1} \wedge\left(\beta_{2} \wedge \beta_{5}+\beta_{3} \wedge \beta_{6}+\beta_{4} \wedge \beta_{7}\right)+\beta_{2} \wedge \beta_{3} \wedge \beta_{4}
$$

We find easily that

$$
\Delta_{4}^{2}=\left[f_{5}, f_{6}, f_{7}\right]=V_{3}, \quad \Delta_{4}^{3}=\left[f_{2}, f_{3}, f_{4}, f_{5}, f_{6}, f_{7}\right]=V_{6}
$$

Further we define $W_{1}=V / V_{6}, W_{4}=V / V_{3}$, and $Z_{3}=V_{6} / V_{3}$. Let us notice that the restriction of $\omega_{4}$ onto $V_{6}$ is the form $\theta \beta_{2} \wedge \beta_{3} \wedge \beta_{4}$. This form obviously induces a 3 -form on the quotient $Z_{3}$, which will be denoted again by $\theta$.

We shall now investigate the group $O_{4}$. It is obvious that any automorphism $\varphi \in O_{4}$ preserves the subspaces $V_{3}$ and $V_{6}$. It is also clear that such $\varphi$ induces an automorphism $\tilde{\varphi} \in G L\left(W_{1}\right)$, an automorphism $\hat{\varphi} \in G L\left(Z_{3}\right)$, and an automorphism $\bar{\varphi} \in G L\left(V_{3}\right)$. The automorphism $\tilde{\varphi}$ has the form $\tilde{\varphi}=c_{\varphi} \cdot i d$, where $c_{\varphi} \in \mathbb{R}^{*}$.

We can define first a homomorphism

$$
\mu: O_{4} \rightarrow \mathbb{R}^{*}, \quad \mu \varphi=c_{\varphi}
$$

It is easy to see that this homomorphism is an epimorphism, and we get a split short exact sequence

$$
0 \rightarrow O_{4}^{+} \rightarrow O_{4} \xrightarrow{\mu} \mathbb{R}^{*} \rightarrow 0
$$

where $O_{4}^{+}=\operatorname{ker} \mu$.
It is also easy to see that if $\varphi \in O_{4}$, then $\hat{\varphi}^{*} \theta=\theta$, which means that $\hat{\varphi} \in S L\left(Z_{3}\right) \cong$ $S L(3, \mathbb{R})$. Consequently, we can define a homomorphism

$$
\nu: O_{4} \rightarrow S L\left(Z_{3}\right), \quad \nu \varphi=\hat{\varphi} .
$$

We shall use only the restriction of $\nu$ to the subgroup $O_{4}^{+}$, which we denote again by $\nu$. This restriction is also an epimorphism, and we obtain a split short exact sequence

$$
0 \rightarrow K \rightarrow O_{4}^{+} \xrightarrow{\nu} S L(3, \mathbb{R}) \rightarrow 0
$$

where $K=\operatorname{ker} \nu$.

It can be shown that the subgroup $K$ consists precisely of elements with the matrix expression

$$
\varphi=\left(\begin{array}{ccccccc}
1 & \varphi_{37}-\varphi_{46} & \varphi_{45}-\varphi_{27} & \varphi_{26}-\varphi_{35} & \varphi_{15} & \varphi_{16} & \varphi_{17} \\
0 & 1 & 0 & 0 & \varphi_{25} & \varphi_{26} & \varphi_{27} \\
0 & 0 & 1 & 0 & \varphi_{35} & \varphi_{36} & \varphi_{37} \\
0 & 0 & 0 & 1 & \varphi_{45} & \varphi_{46} & \varphi_{47} \\
0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 1
\end{array}\right)
$$

We shall consider first a homomorphism

$$
\tau_{2}: K \rightarrow \mathbb{R}, \quad \tau_{2} \varphi=\varphi_{37}-\varphi_{46}
$$

This homomorphism is an epimorphism, and we get a split short exact sequence

$$
0 \rightarrow L_{2} \rightarrow K \xrightarrow{\tau_{2}} \mathbb{R} \rightarrow 0,
$$

where $L_{2}=\operatorname{ker} \tau_{2}$. Next, we define a homomorphism

$$
\tau_{3}: L_{2} \rightarrow \mathbb{R}, \quad \tau_{3} \varphi=\varphi_{45}-\varphi_{27}
$$

Again this homomorphism is an epimorphism, and we have a split short exact sequence

$$
0 \rightarrow L_{3} \rightarrow L_{2} \xrightarrow{\tau_{3}} \mathbb{R} \rightarrow 0
$$

where $L_{3}=\operatorname{ker} \tau_{3}$. Finally, we define a homomorphism

$$
\tau_{4}: L_{3} \rightarrow \mathbb{R}, \quad \tau_{4} \varphi=\varphi_{26}-\varphi_{35}
$$

This homomorphism is also an epimorphism, and we obtain a split short exact sequence

$$
0 \rightarrow L_{4} \rightarrow L_{3} \xrightarrow{\tau_{4}} \mathbb{R} \rightarrow 0
$$

where $L_{4}=\operatorname{ker} \tau_{4}$.
In order to describe the subgroup $L_{4}$, we consider the restriction homomorphism

$$
\rho: L_{4} \rightarrow G L\left(V_{6}\right), \quad \rho \varphi=\check{\varphi}=\varphi \mid V_{6} .
$$

The image of this homomorphism is a commutative subgroup of $G L\left(V_{6}\right)$ which is isomorphic as a Lie group to $\mathbb{R}^{6}$. This time we get a split short exact sequence

$$
0 \rightarrow M \rightarrow L_{4} \xrightarrow{\rho} \mathbb{R}^{6} \rightarrow 0
$$

where $M=\operatorname{ker} \rho$. It is not difficult to see that $M$ is isomorphic as a Lie group to $\mathbb{R}^{3}$.
Summarizing we obtain

## 7. Proposition.

$$
O_{4}=\left[\left(\left(\left(\left[\mathbb{R}^{3} \ltimes \mathbb{R}^{6}\right] \ltimes \mathbb{R}\right) \ltimes \mathbb{R}\right) \ltimes \mathbb{R}\right) \ltimes S L(3, \mathbb{R})\right] \ltimes \mathbb{R}^{*}
$$

with $\operatorname{dim} O_{4}=21$.

Type 5. The form $\omega_{5}$.
We have here

$$
\begin{aligned}
\Delta_{5}^{2}=\{0\}, \quad \Delta_{5}^{3}= & \left\{v \in V ;-c_{1}^{2}-c_{2}^{2}-c_{3}^{2}+c_{4}^{2}+c_{5}^{2}+c_{6}^{2}+c_{7}^{2}=0\right\} \\
& \left(\iota(v) \omega_{5}\right) \wedge\left(\iota(w) \omega_{5}\right) \wedge \omega_{5}=
\end{aligned}
$$

$=\left(-c_{1} d_{1}-c_{2} d_{2}-c_{3} d_{3}+c_{4} d_{4}+c_{5} d_{5}+c_{6} d_{6}+c_{7} d_{7}\right) \alpha_{1} \wedge \alpha_{2} \wedge \alpha_{3} \wedge \alpha_{4} \wedge \alpha_{5} \wedge \alpha_{6} \wedge \alpha_{7}$.
The form $\omega_{5}$ is well known. It arises in the following way. We recall that the algebra $\widetilde{\mathbb{C} a}$ of pseudoCayley numbers is defined as the double of the algebra of pseudoquaternions. Let $(\cdot, \cdot)$ denote the standard scalar product on the algebra of pseudoCayley numbers. We take $V=\operatorname{Im} \widetilde{\mathbb{C} a}$. Then for any $v_{1}, v_{2}, v_{3} \in V$ we have

$$
\omega_{5}\left(v_{1}, v_{2}, v_{3}\right)=\left(v_{1} v_{2}, v_{3}\right)
$$

It is obvious that $A u t(\widetilde{\mathbb{C} a}) \subset O_{5}$, where $A u t(\widetilde{\mathbb{C} a})$ denotes the group of automorphisms of the algebra of pseudoCayley numbers. In fact, it can be proved that these two groups coincide. Moreover, the group $A u t(\widetilde{\mathbb{C} a})$ is isomorphic with the group $\tilde{G}_{2}$, the noncompact dual of the exceptional Lie group $G_{2}$. Thus, we have
8. Proposition. $O_{5}=\tilde{G}_{2}$ with $\operatorname{dim} O_{5}=14$.

## Type 6. The form $\omega_{6}$.

Here we have

$$
\begin{gathered}
\Delta_{6}^{2}=\left[e_{7}\right], \quad \Delta_{6}^{3}=\left[e_{3}, e_{4}, e_{5}, e_{6}, e_{7}\right] \\
\left(\iota(v) \omega_{6}\right) \wedge\left(\iota(w) \omega_{6}\right) \wedge \omega_{6}=6\left(c_{1} d_{1}+c_{2} d_{2}\right) \alpha_{1} \wedge \cdots \wedge \alpha_{7}
\end{gathered}
$$

We denote $V_{1}=\Delta_{6}^{2}, V_{5}=\Delta_{6}^{3}, W_{2}=V / V_{5}$, and $Z_{4}=V_{5} / V_{1}$. We shall consider on $V$ the quadratic form $Q(v)=c_{1}^{2}+c_{2}^{2}$, and we denote the corresponding bilinear form by $B$. $Q$ induces a definite form $Q_{2}$ on $W_{2}$. The corresponding bilinear form we denote by $B_{2}$.

The insertion $v \in V_{1} \mapsto \iota(v) \omega_{6}$ induces an isomorphism

$$
\kappa: V_{1} \rightarrow \Lambda^{2} W_{2}^{*}
$$

Furthermore, the insertion $v \mapsto\left(\iota(v) \omega_{6}\right) \mid V_{5}$ induces a monomorphism

$$
\lambda: W_{2} \rightarrow \Lambda^{2} Z_{4}^{*} .
$$

We denote $\lambda e_{1}=\sigma_{1}, \lambda e_{2}=\sigma_{2}$. Introducing on $Z_{4}$ an auxiliary positive definite bilinear form $B_{4}$ in such a way that with respect to it $e_{3}, e_{4}, e_{5}, e_{6}$ is an orthonormal basis, we can find uniquely determined endomorphisms $E, F$ of $Z_{4}$ such that for every $w, w^{\prime} \in Z_{4}$ we have

$$
\sigma_{1}\left(w, w^{\prime}\right)=B_{4}\left(E w, w^{\prime}\right), \quad \sigma_{2}\left(w, w^{\prime}\right)=B_{4}\left(F w, w^{\prime}\right)
$$

An easy computation shows that $E^{2}=-I, F^{2}=-I$ and $E F=-F E$. Setting $G=E F$, we have the relations

$$
\begin{gathered}
E^{2}=-I, \quad F^{2}=-I, \quad G^{2}=-I \\
E F=-F E=G, \quad F G=-G F=E, \quad G E=-E G=F
\end{gathered}
$$

which show that the automorphisms $I, E, F, G$ generate the algebra $\mathbb{H}$ of quaternions.
Any automorphism $\varphi \in O_{6}$ induces an automorphisms $\bar{\varphi}$ of $Z_{4}$. We define a homomorphism

$$
\rho: O_{6} \rightarrow G L\left(Z_{4}\right), \quad \rho \varphi=\bar{\varphi}
$$

Similarly any automorphism $\varphi \in O_{6}$ induces an automorphisms $\tilde{\varphi}$ of $W_{2}$. Obviously, $\tilde{\varphi} \in C O\left(Q_{2}\right)$. This means that we can define a homomorphism

$$
\mu: O_{6} \rightarrow C O\left(Q_{2}\right), \quad \mu \varphi=\tilde{\varphi}
$$

We shall start with the homomorphism

$$
\operatorname{det} \mu: O_{6} \rightarrow \mathbb{R}^{*}
$$

This homomorphism is an epimorphism, and we have a split short exact sequence

$$
0 \rightarrow O_{6}^{1} \rightarrow O_{6} \xrightarrow{\operatorname{det} \mu} \mathbb{R}^{*} \rightarrow 0
$$

where $O_{6}^{1}=\operatorname{ker}(\operatorname{det} \mu)$.
Next, we are going to investigate a restriction of the above homomorphism $\mu$, namely the homomorphism

$$
\mu: O_{6}^{1} \rightarrow S O\left(Q_{2}\right)
$$

It can be proved that this homomorphism is an epimorphism, and because $S O\left(Q_{2}\right) \equiv$ $S O(2)$, we obtain a split short exact sequence

$$
0 \rightarrow L \rightarrow O_{6}^{1} \xrightarrow{\mu} S O(2) \rightarrow 0,
$$

where $L=\operatorname{ker} \mu$.
Now, we can consider a restriction of the homomorphism $\rho$, namely the homomorphism $\rho: L \rightarrow G L\left(Z_{4}\right)$. Considering $Z_{4}$ as an 1-dimensional quaternionic vector
space, we find that the image of the homomorphism $\rho$ is isomorphic to the group $S L(2, \mathbb{C})$. We get then a split short exact sequence

$$
0 \rightarrow M \rightarrow L \xrightarrow{\rho} S L(2, \mathbb{C}) \rightarrow 0
$$

where $M=\operatorname{ker} \rho$.
The matrix of an automorphism $\varphi \in M$ with respect to the basis $e_{1}, \ldots, e_{7}$ has the form

$$
\varphi=\left(\begin{array}{ccccccc}
1 & 0 & \varphi_{13} & \varphi_{14} & \varphi_{15} & \varphi_{16} & \varphi_{17} \\
0 & 1 & \varphi_{23} & \varphi_{24} & \varphi_{25} & \varphi_{26} & \varphi_{27} \\
0 & 0 & 1 & 0 & 0 & 0 & \varphi_{37} \\
0 & 0 & 0 & 1 & 0 & 0 & \varphi_{47} \\
0 & 0 & 0 & 0 & 1 & 0 & \varphi_{57} \\
0 & 0 & 0 & 0 & 0 & 1 & \varphi_{67} \\
0 & 0 & 0 & 0 & 0 & 0 & 1
\end{array}\right)
$$

On the other hand, an automorphism of this form is not necessarily an element of $M$. It belongs to $M$ if and only if it belongs to $O_{6}$. An easy computation shows that $\varphi \in M$ if and only if the following equations are satisfied

$$
\begin{aligned}
\varphi_{37} & =-\varphi_{15}-\varphi_{26} \\
\varphi_{47} & =-\varphi_{16}+\varphi_{25} \\
\varphi_{57} & =\varphi_{13}-\varphi_{24} \\
\varphi_{67} & =\varphi_{14}+\varphi_{23}
\end{aligned}
$$

We shall consider first the mapping

$$
\nu_{1}: M \rightarrow \mathbb{R}^{2}, \quad \nu_{1} \varphi=\left(\varphi_{37}, \varphi_{47}\right)
$$

It is not difficult to prove that this mapping is an epimorphism of the group $M$ onto the commutative group $\mathbb{R}^{2}$. In this way we obtain a split short exact sequence

$$
0 \rightarrow N_{1} \rightarrow M \xrightarrow{\nu_{3}} \mathbb{R}^{2} \rightarrow 0
$$

where $N_{1}=\operatorname{ker} \nu_{1}$. Next we define a mapping

$$
\nu_{2}: N_{1} \rightarrow \mathbb{R}^{2}, \quad \nu_{2} \varphi=\left(\varphi_{57}, \varphi_{67}\right)
$$

It is again not difficult to prove that this mapping is an epimorphism of the group $N_{1}$ onto the commutative group $\mathbb{R}^{2}$. We obtain a split short exact sequence

$$
0 \rightarrow N_{2} \rightarrow N_{1} \xrightarrow{\nu_{2}} \mathbb{R}^{2} \rightarrow 0
$$

where $N_{2}=\operatorname{ker} \nu_{2}$. Moreover, one can easily see that $N_{2}$ is a commutative Lie group isomorphic with $\mathbb{R}^{6}$.

Finally, we obtain

## 9. Proposition.

$$
O_{6}=\left[\left(\left(\left(\mathbb{R}^{6} \ltimes \mathbb{R}^{2}\right) \ltimes \mathbb{R}^{2}\right) \ltimes S L(2, \mathbb{C})\right) \ltimes S O(2)\right] \ltimes \mathbb{R}^{*},
$$

with $\operatorname{dim} O_{6}=18$.

Type 7. The form $\omega_{7}$.
Here we have

$$
\Delta_{7}^{2}=\{0\}, \quad \Delta_{7}^{3}=\left[e_{5}, e_{6}, e_{7}\right]
$$

and we denote $V_{3}=\left[e_{5}, e_{6}, e_{7}\right]$, and $W_{4}=V / V_{3}$. Moreover,

$$
\left(\iota(v) \omega_{7}\right) \wedge\left(\iota(w) \omega_{7}\right) \wedge \omega_{7}=\left(c_{1} d_{1}+c_{2} d_{2}+c_{3} d_{3}+c_{4} d_{4}\right) \alpha_{1} \wedge \cdots \wedge \alpha_{7}
$$

Consequently, we consider on $V$ the bilinear form

$$
B(v, w)=c_{1} d_{1}+c_{2} d_{2}+c_{3} d_{3}+c_{4} d_{4} .
$$

The kernel of $B$ is the subspace $V_{3}$, and therefore there is an induced positive definite bilinear form $B_{4}$ on $W_{4}$. The corresponding quadratic form we denote by $Q_{4}$.

It is easy to see that the mapping $v \in V_{3} \mapsto \iota(v) \omega_{7}$ induces a monomorphism

$$
\lambda: V_{3} \rightarrow \Lambda^{2} W_{4}^{*}
$$

We denote

$$
\lambda\left(e_{5}\right)=\sigma_{1}, \quad \lambda\left(e_{6}\right)=\sigma_{2}, \quad \lambda\left(e_{7}\right)=\sigma_{3}
$$

There are uniquely defined automorphisms $E, F, G$ of $W_{4}$ such that

$$
\sigma_{1}\left(w, w^{\prime}\right)=B_{4}\left(E w, w^{\prime}\right), \quad \sigma_{2}\left(w, w^{\prime}\right)=B_{4}\left(F w, w^{\prime}\right), \quad \sigma_{3}\left(w, w^{\prime}\right)=B_{4}\left(G w, w^{\prime}\right)
$$

for every $w, w^{\prime} \in W_{4}$. It is easy to verify that

$$
E^{2}=F^{2}=G^{2}=-I
$$

$$
E F=-F E=-G, \quad F G=-G F=-E \quad G E=-E G=-F,
$$

which shows that the associative subalgebra of $\operatorname{End}\left(W_{4}\right)$ generated by $I, E, F$, and $G$ is isomorphic with the algebra $\mathbb{H}$ of quaternions. This means that $W_{4}$ can be considered as an 1-dimensional quaternionic vector space.

The scalar product $B_{4}$ induces a scalar product on $W_{4}^{*}$ and this in turn induces a scalar product on $\Lambda^{2} W_{4}^{*}$. We shall denote these products again by $B_{4}$. We find easily that the elements $\sigma_{1}, \sigma_{2}, \sigma_{3}$ are orthonormal with

$$
B_{4}\left(\sigma_{1}, \sigma_{1}\right)=1, \quad B_{4}\left(\sigma_{2}, \sigma_{2}\right)=1, \quad B_{4}\left(\sigma_{3}, \sigma_{3}\right)=1
$$

Using the monomorphism $\lambda$, we transfer the scalar product $B_{4}$ from $\Lambda^{2} W_{4}^{*}$ to $V_{3}$. This product on $V_{3}$ we denote by $B_{3}$. With respect to $B_{3}$ the basis $e_{5}, e_{6}, e_{7}$ is an orthonormal basis with

$$
B_{3}\left(e_{1}, e_{1}\right)=1, \quad B_{3}\left(e_{2}, e_{2}\right)=1, \quad B_{3}\left(e_{3}, e_{3}\right)=1
$$

The corresponding quadratic form we shall denote by $Q_{3}$. Now, we can see that $\lambda: V_{3} \rightarrow \Lambda^{2} W_{4}^{*}$ is an isometry into.

We can start to investigate the group $O_{7}$ of automorphisms of the form $\omega_{7}$. Any element $\varphi \in O_{7}$ preserves the subspace $V_{3}$, and induces an automorphism $\tilde{\varphi}$ of $W_{4}$. Obviously, $\tilde{\varphi}$ preserves up to a positive multiple the bilinear form $B_{4}$. Consequently, we can define a homomorphism

$$
\mu: O_{7} \rightarrow C O\left(Q_{4}\right), \quad \mu \varphi=\tilde{\varphi}
$$

where

$$
C O\left(Q_{4}\right)=\left\{\chi \in G L\left(W_{4}\right) ; \exists d>0 \text { such that } Q_{4}(\chi w)=d Q_{4}(w) \text { for all } w \in W_{4}\right\}
$$

For every $\varphi \in O_{7}$ we find easily the formula

$$
\lambda \varphi=\Lambda^{2}\left(\varphi^{-1}\right) \lambda
$$

This means that for every $v \in V_{3}$ we have

$$
\begin{gathered}
B_{3}(\varphi v, \varphi v)=B_{4}(\lambda \varphi v, \lambda \varphi v)=B_{4}\left(\Lambda^{2}\left(\varphi^{-1}\right) \lambda v, \Lambda^{2}\left(\varphi^{-1}\right) \lambda v\right)= \\
=d B_{4}(\lambda v, \lambda v)=d B_{3}(v, v)
\end{gathered}
$$

which means that the restriction $\bar{\varphi}=\varphi \mid V_{3}$ preserves the bilinear form $B_{3}$ up to a positive multiple. Therefore we can define the restriction homomorphisms

$$
\rho: O_{7} \rightarrow C O\left(Q_{3}\right), \quad \rho \varphi=\bar{\varphi}=\varphi \mid V_{3}
$$

where

$$
C O\left(Q_{3}\right)=\left\{\psi \in G L\left(V_{3}\right) ; \exists c>0 \text { such that } Q_{3}(\psi v)=c Q_{3}(v) \text { for all } v \in V_{3}\right\}
$$

It is possible to prove that the image of the homomorphism $\rho$ is the subgroup $\operatorname{CSO}\left(Q_{3}\right)$. Consequently, we obtain a split short exact sequence

$$
0 \rightarrow K \rightarrow O\left(\omega_{7}\right) \xrightarrow{\rho} C S O\left(Q_{3}\right) \rightarrow 0
$$

where $K=\operatorname{ker} \rho$. We shall now consider the restriction $\mu: K \rightarrow C O\left(Q_{4}\right)$ of the homomorphism $\mu$. It can be proved that an element $\psi \in C O\left(Q_{4}\right)$ belongs to the image of $\mu$ if and only if $\psi$ is an automorphism of the 1 -dimensional quaternionic
vector space $W_{4}$ preserving the bilinear form $B_{4}$. Consequently, the image of $\mu$ can be identified with the group

$$
S^{3}=\{A \in \mathbb{H} ;(A, A)=1\}
$$

where ( $\cdot, \cdot$ ) denotes the standard scalar product on $\mathbb{H}$. In this way we get a homomorphism $\mu: K \rightarrow S^{3}$, and our standard considerations show that this homomorphism is an epimorphism. Thus, we obtain a split short exact sequence

$$
0 \rightarrow L \rightarrow K \xrightarrow{\mu} S^{3} \rightarrow 0
$$

where $L=\operatorname{ker} \mu$.
Any element $\varphi \in L$ determines an endomorphism $D_{\varphi}: V \rightarrow V$ such that $D_{\varphi} V_{4} \subset$ $V_{3}, D_{\varphi} \mid V_{3}=0$, and

$$
\begin{gathered}
\varphi e_{1}=e_{1}+D_{\varphi} e_{1}, \quad \varphi e_{2}=e_{2}+D_{\varphi} e_{2}, \quad \varphi e_{3}=e_{3}+D_{\varphi} e_{3}, \quad \varphi e_{4}=e_{4}+D_{\varphi} e_{4} \\
\varphi e_{5}=e_{5}, \quad \varphi e_{6}=e_{6}, \quad \varphi e_{7}=e_{7}
\end{gathered}
$$

It is obvious that the group

$$
\left\{i d+D ; D \in E n d(V) \text { with } D V_{4} \subset V_{3} \text { and } D \mid V_{3}=0\right\}
$$

is commutative. This shows that also the group $L$ is commutative. Considering an automorphism $\varphi=i d+D$, we can easily see that

$$
\omega_{7}\left(\varphi e_{i}, \varphi e_{j}, \varphi e_{k}\right)=\omega_{7}\left(e_{i}, e_{j}, e_{k}\right) \quad \text { if }\{i, j, k\} \cap\{5,6,7\} \neq \emptyset
$$

This means that $\varphi=i d+D \in O_{7}$ if and only if

$$
\omega_{7}\left(\varphi e_{i}, \varphi e_{j}, \varphi e_{k}\right)=\omega_{7}\left(e_{i}, e_{j}, e_{k}\right)=0 \quad \text { for all } i, j, k \in\{1,2,3,4\}
$$

We can find easily that $\varphi=i d+D \in O_{7}$ if and only if the following four equations are satisfied:

$$
\begin{aligned}
& \omega_{7}\left(D e_{1}, e_{2}, e_{3}\right)+\omega_{7}\left(e_{1}, D e_{2}, e_{3}\right)+\omega_{7}\left(e_{1}, e_{2}, D e_{3}\right)=0 \\
& \omega_{7}\left(D e_{1}, e_{2}, e_{4}\right)+\omega_{7}\left(e_{1}, D e_{2}, e_{4}\right)+\omega_{7}\left(e_{1}, e_{2}, D e_{4}\right)=0 \\
& \omega_{7}\left(D e_{1}, e_{3}, e_{4}\right)+\omega_{7}\left(e_{1}, D e_{3}, e_{4}\right)+\omega_{7}\left(e_{1}, e_{3}, D e_{4}\right)=0 \\
& \omega_{7}\left(D e_{2}, e_{3}, e_{4}\right)+\omega_{7}\left(e_{2}, D e_{3}, e_{4}\right)+\omega_{7}\left(e_{2}, e_{3}, D e_{4}\right)=0
\end{aligned}
$$

Hence we can conclude that $L$ is a Lie group isomorphic with the Lie group $\mathbb{R}^{8}$. Finally, we obtain

## 10. Proposition.

$$
O_{7}=\left(\mathbb{R}^{8} \ltimes S^{3}\right) \ltimes C S O(3) .
$$

with $\operatorname{dim} O\left(\omega_{7}\right)=15$.

Type 8. The form $\omega_{8}$.
We have here

$$
\begin{aligned}
& \qquad \Delta_{8}^{2}=\{0\}, \quad \Delta_{8}^{3}=\{0\}, \\
& \qquad\left(\iota(v) \omega_{8}\right) \wedge\left(\iota(w) \omega_{8}\right) \wedge \omega_{8}= \\
& =\left(c_{1} d_{1}+c_{2} d_{2}+c_{3} d_{3}+c_{4} d_{4}+c_{5} d_{5}+c_{6} d_{6}+c_{7} d_{7}\right) \alpha_{1} \wedge \alpha_{2} \wedge \alpha_{3} \wedge \alpha_{4} \wedge \alpha_{5} \wedge \alpha_{6} \wedge \alpha_{7} \\
& \text { The form } \omega_{8} \text { is the best known one. It arises in the following way. We recall } \\
& \text { that the algebra } \mathbb{C} a \text { of Cayley numbers is defined as the double of the algebra of } \\
& \text { quaternions. Let }(\cdot, \cdot) \text { denote the standard scalar product on the algebra of Cayley } \\
& \text { numbers. We take } V=\operatorname{Im} \mathbb{C} a \text {. Then for any } v_{1}, v_{2}, v_{3} \in V \text { we have }
\end{aligned}
$$

$$
\omega_{8}\left(v_{1}, v_{2}, v_{3}\right)=\left(v_{1} v_{2}, v_{3}\right)
$$

It is obvious that $\operatorname{Aut}(\mathbb{C} a) \subset O_{8}$, where $\operatorname{Aut}(\mathbb{C} a)$ denotes the group of automorphisms of the algebra of Cayley numbers. In fact, it can be proved that these two groups coincide. Moreover, the group $\operatorname{Aut}(\mathbb{C} a)$ is isomorphic with the exceptional Lie group $G_{2}$. Thus, we have
11. Proposition. $O_{8}=G_{2}$ with $\operatorname{dim} O_{8}=14$.
