## ON BOUNDED SOLUTIONS OF NONLINEAR ORDINARY DIFFERENTIAL EQUATIONS <br> Moses A. BOUDOURIDES

Abstract: We prove the existence and an asymptotic property of bounded solutions of the nonlinear differential equation (in a Banach space $E$ and with the independent variable $t \in[0, \infty)$ )

$$
x^{\prime}=A(t) x+f(t, x)
$$

under the assumption that the non-homogeneous linear equation $x^{\prime}=A(t) x+b(t)$
has at least one bounded solution for each $b$ belonging to a function Banach space B.

Key words: Ordinary differential equations in Banach spaces, function spaces, admissibility, successive approximations.

Classification: 34A34, 34G20, 34C11

1. Introduction. The object of the present article is the study of the relations between the solutions of the following equations

$$
\begin{equation*}
x^{\prime}=A(t) x \tag{1}
\end{equation*}
$$

$x^{\prime}=A(t) x+b(t)$

$$
\begin{equation*}
x^{\prime}=A(t) x+f(t, x) \tag{2}
\end{equation*}
$$

where $t \in J=[0, \infty) ; x, b, f \in E$, a real Banach space; $A(t)$, for every fixed $t$, is a continuous linear operator (endomorphism) of $E$ into itself; $A(t), b(t)$ are locally integrable (in the Bochner sense).

In the years 1930-1935, O. Perron, K.P. Persidakii and I.G. Malkin (cf. [4] for references) established (among other results) the equivalence of the following properties (in the case $\operatorname{dim} E<\infty, A(t)$ continuous)
(PI) for each bounded continuous b all the solutions of (2) are bounded;
(P2) for each $f$ continuous, $\|f(t, x)\| \leqslant \beta, \| f(t, x)$ $f(t, y)\|\leqslant \gamma\| x-y \|$, with sufficiently small $\beta, \gamma$, , all the solutions of (3) with sufficiently small \|x(0)\| are bounded;
(P3) there exist positive constants $N$, $\nu$ such that for any solution $x$ of (1) and for any $t \geqq t_{0} \geqq 0$ we have

$$
\|x(t)\| \leqq N e^{-\nu\left(t-t_{0}\right)}\left\|x\left(t_{0}\right)\right\|
$$

In the years 1958-1959, J.L. Massera and J.J. Schaffer (cf. [3], [4]) generalized these properties (in the case of $\operatorname{dim} E=\infty$ and of Carathéodory type conditions), considering a general category of function spaces.

The purpose of this article is to establish the equivalence of (P1) and (P2) in the frame of the general function spaces of [4] and in the case when $f$ is such that $\| f(t, x)$ -- $f(t, y) \| \leqslant(t,\|x-y\|)$, where $\omega(t, \cdot)$ is an appropriate non-decreasing function. To this end, we first extend Coppel's equivalent criterion to (PI). Finally, we obtain sufficient conditions such that for every bounded solution $x$ of (3) $\lim _{t \rightarrow \infty}\|x(t)\|=0$.
2. Notation and preliminaries. Let $X$ be a generic Banach space with norm $\|\cdot\| X^{\text {. We denote by }} X^{*}$ its dual and by (.,.)
the duality pairing of $X$ and $X^{*}$; the norm of $X^{*}$ is denoted again by $\|\cdot\|_{X^{*}}$. We denote by $\widetilde{\mathrm{x}}$ the space of continuous endomorphisms of $X$ and again by $\|\cdot\|_{\tilde{X}}$ the norm of $\tilde{X}$. If $A \epsilon$ $\epsilon \widetilde{X}$, we denote by $A^{*} \in \tilde{X}^{*}$ its adjoint operator.

For the Banach space $E$ we write $\|\cdot\|_{\mathbf{E}}=\|\cdot\|$. For any $\mathbf{a}>0$, we write $S_{a}=\{\mathbf{x} \in E ;\|\mathbf{x}\|<\mathbf{a}\}$.

By $C=C(E)$ we denote the Banach space of bounded continuous functions $u: \mathcal{J} \rightarrow E$ with the norm $\|u\|_{C}=\sup \{\|u(s)\|:$ $: s \in J\}$. For any $a>0$, we write $\Sigma_{a}=\left\{u \in C:\|u\|_{C}<a\right\}$.

By $L^{p}=L^{p}(E), l \leqslant p<\infty$, we denote the Banach space of strongly measurable functions $u: J \rightarrow E$ such that $\int_{J}\|u(s)\|^{p} d s<$ $<\infty$ with the norm $\|u\|_{L^{p}}=\left\{\int_{J}\|u(s)\|^{p}{ }_{d s}\right\}^{1 / p}$. By $L^{\infty}=L^{\infty}(E)$ we denote the Banach space of strongly measurable functions $u: J \rightarrow E$ such that ess $\sup \{\|u(s)\|: s \in J\}<\infty$ with the norm $\|u\|_{L^{\infty}}=\operatorname{ess} \sup \{\|u(s)\|: s \in J\}$.

By $L=L(E)$ we denote the space of strongly measurable functions $u: J \rightarrow E$, Bochner integrable in every finite subinterval I of $J$, with the topology of the convergence in the mean on every such $I$.

Let $B(R)$ be a Banach space of measurable functions $u: J \rightarrow$ $\rightarrow$ R such that
(i) $B(R)$ is stronger than $L(R)$ (cf. [4], p.35);
(ii) if $u \in L^{\infty}(R)$ with compact support, then $u \in B(R)$;
(iii) if $u \in B(R)$ and $v: J \longrightarrow R$ measurable and such that $|v| \leqq|u|$, then $v \in B(R)$ and $\|v\|_{B(R)} \leqq\|u\|_{B(R)}$.

By the associate space $B^{*}(R)$ we denote the Banach apace of all measurable functions $v: J \longrightarrow R$ such that

$$
\sup \left\{\int_{J}|u(s) v(s)| d s: u \in B(R),\|u\|_{B(R)} \leqq 1\right\}<\infty
$$

with norm $\|\nabla\|_{B *}(R)=\sup \left\{\int_{J}|u(s) \nabla(s)| d e: u \in B(R),\|u\|_{B(R)} \leq\right.$ $\leqslant 1\}$. According to Theorem 22.M of [4], the following "Holder's Inequality" holds: if $u \in B(R)$ and $\nabla \in B^{*}(R)$, then $|u v| \in L^{1}(R)$ and

$$
\int_{J}|u(s) v(s)| d s \leq\|u\|_{B(R)}\|v\|_{B^{*}(R)} .
$$

We denote by $B=B(E)\left(B^{*}=B^{*}(E)\right)$ the Banach space of all strongly measurable functions $u: J \rightarrow E$ such that $\|u\| E$ $\in B(R)\left(\|u\| \in B^{*}(R)\right)$ provided with the norm $\|u\|_{B}=$ $=\| \| u \|_{B(R)}\left(\|u\|_{B^{*}}=\| \| u\| \|_{B^{*}(R)}\right)$.

Let $A \in L(\widetilde{E})$ and let $E_{0}$ be the set of all points of $E$ which are values for $t=0$ of bounded solutions of (1).

We assume that $E_{0}$ is closed. Then according to Theorem 4.1 of [3], there exists $S>0$ such that every bounded solution $x$ of (1) satisfies the estimate

$$
\|x\|_{C} \leqslant S\|x(0)\|
$$

Moreover, we assume that $E_{0}$ has a closed complement $E_{1}$. Let $P$ be the projection of $E$ onto $E_{0}$. Furthermore, let $U(t)$ be the fundamental solution of (I) such that $U(O)=I$. For any $t \in J$ we define a function $G(t, \cdot) \in L(\widetilde{E})$ by

$$
G(t, s)= \begin{cases}U(t) P U^{-1}(s) & \text { for } 0 \leqq s \leqq t \\ -U(t)(I-P) U^{-1}(s) & \text { for } s \geqq t .\end{cases}
$$

3. The Non-homogeneous Linear Equation. The pair of Banach spaces ( $B, C$ ) is called admissible (cf. [4], p. 127), if for every $b \in B$ there exists at least one bounded solution of (2). Then by Theorem 51.E of [4] there exists a constant $K>0$
such that for every $b \in B$ the equation (2) has a unique bounded solution $x$ with $x(0) \in E_{1}$ and $\|x\|_{C} \leq K\|b\|_{B}$. Moreover, by Theorem 52.J of [4] for every $b \in B$ with compact support the unique bounded solution $x$ of (2) with $x(0) \in E_{1}$ and $\|x\|_{C} \leqq K\|b\|_{B}$ is represented by $x(t)=\int_{\mathcal{J}} G(t, s) b(s) d s$.

Theorem 1. Let ( $B, C$ ) be admissible. Then there exists a constant $K>0$ such that, for any $t \in J, G(t, \cdot) \in B^{*}(E)$ and $\|G(t, \cdot)\|_{B *(\widetilde{E})} \leqq K$.

Proof. Let $b \in B$ with compact support. Suppose that $b$ vanishes for $t>T$, where $T$ is arbitrarily fixed. By the remarks preceding the theorem, there exists a constant $K>0$ such that for any $t \in J$

$$
\begin{gathered}
\left\|\int_{0}^{T} G(t, s) b(s) d s\right\| \leqq K\|b\|_{B^{\prime}} \\
\text { However, for any } x^{*} \in E^{*},\left\|x^{*}\right\| \leqq 1 \text {, and any } t \in J \\
\left|\int_{0}^{T}\left(b(s), G^{*}(t, s) x^{*}\right) d s\right|
\end{gathered}
$$

and as $G^{*}(t, \cdot) x^{*} \in L\left(E^{*}\right)$ for $t \in J$, Theorem $22 . U$ of [4] implies that $G^{*}(t, \cdot) x^{*} \in B^{*}\left(E^{*}\right)$ for $t \in J$ and

$$
\left\|G^{*}(t, \cdot) x^{*}\right\|_{B^{*}\left(E^{*}\right)} \leqq K \text { for } t \in J .
$$

Therefore, we obtain, for any $t \in J$,

$$
\begin{aligned}
\|G(t, \cdot)\|_{B^{*}(\tilde{E})} & =\left\|G^{*}(t, \cdot)\right\|_{B^{*}\left(\tilde{E}^{*}\right)} \\
& =\sup \left\{\left\|G^{*}(t, \cdot) x^{*}\right\|_{B^{*}\left(E^{*}\right)}: x^{*} \in E^{*},\|x *\| \leqq 1\right\} \\
& \leqq K .
\end{aligned}
$$

Remark 1. Theorem 1 generalizes the results of Coppel
[2] for $B=C\left(R^{n}\right)$ and $B=L^{1}\left(R^{n}\right)$, Conti $[1]$ for $B=L^{p}\left(R^{n}\right)$, $1 \leqq p \leqq \infty$, and Szufla [5] for $B=L_{\Phi}(E)$ (Orlicz spaces).

In particular, the above theorem implies that if ( $B, C$ ) is admissible, then the (Bochner) integral $\int_{\mathcal{J}} G(t, s) b(s) d s$ exists for any $b \in B$.

Theorem 2. Let $(B, C)$ be admissible. If $b \in B$, then $a$ function $x: J \longrightarrow E$ is a boundea solution of (2) if and only if

$$
\mathbf{x}(t)=U(t) P \mathbf{x}(0)+\int_{\mathcal{J}} G(t, s) b(s) d s .
$$

Proof. Since the sufficiency is easily seen to hold, we will only prove the necessity. So, let $x$ a bounded solution of (2) and let $b \in B$. Writing
$y(t)=x(t)-U(t) P x(0)-\int_{J} G(t, s) b(s) d s$, it is clear that $y$ is a bounded solution of (1) with
$y(0)=x(0)-\operatorname{Px}(0)+(I-P) \int_{J} U^{-1}(s) b(s) d s$,
i.e. $y(0) \in E_{1}$. Therefore, $y=0$.
4. The Nonlinear Equation. Consider the nonlinear equation (3), where we assume that $\mathrm{f}: \mathrm{J} \times \mathrm{S}_{\mathrm{a}} \rightarrow \mathrm{E}, 0<a \leqq \infty$, is such that
(fi) $f(t, x)$ is strongly measurable in $t$ for all $x \in S_{a}$ and continuous in $x$ for $t \in J$;
(f2) $f(\cdot, 0) \in B$.
Let $\omega: J \times[0,2 a) \rightarrow R$ be such that
( $\omega 1$ ) $\omega(\cdot, r) \in B(R)$ for all $r \in[0,2 a)$;
( $\omega$ 2) $\omega(t, r)$ is continuous nondecreasing in $\mathbf{r}$ for $t \in J$;
and defining $\Omega:[0,2 a) \rightarrow R$ by $\Omega(r)=K\|\omega(\cdot, r)\|_{B(R)}$ (where $K$ as in Theorem 1) we assume
( $\omega 3$ ) $\mathbf{r}=0$ is the only fixed point of $\Omega$ in $[0,2 a)$;
( $\omega 4$ ) for each $r \in[0,2 a), \Omega(r) \leqq r$.
Theorem 3. Let ( $B, C$ ) be admissible. Suppose that $f$ satisfies (fl) and (f2) and that there exists a function $\omega$ satisfying ( $\omega 1$ )-( $\omega 4$ ) such that for any $t \in J$ and $x, y \in S_{a}$

$$
\begin{equation*}
\|f(t, x)-f(t, y)\| \leqslant \omega(t,\|x-y\|) \tag{4}
\end{equation*}
$$

Then, if

$$
\begin{equation*}
\|f(\cdot, 0)\|_{B}<K^{-1}(a-\Omega(a)) \tag{5}
\end{equation*}
$$

there exists, for any $\xi \in \mathbf{E}_{0}$ such that

$$
\|\xi\|<b=S^{-1}\left(a-\Omega(a)-K\|f(\cdot, 0)\|_{B}\right),
$$

a unique bounded solution $x(\cdot ; \xi)$ of (3) such that $x(\cdot ; \xi) \in \sum_{a}$ and $\operatorname{Px}(0 ; \xi)=\xi$. Moreover, the mapping $\xi \mapsto x(0 ; \xi)$ is continuous in $F_{0}=\left\{\xi \in E_{0}:\|\xi\|<b\right\}$ and it can be extended to a homeomorohism $H$ of $F_{0}+E_{1}$ onto itself which leaves the affine subspaces $\xi+E_{1}, \xi \in F_{0}$, invariant.

Proof. First we remark that if $z \in \Sigma_{a}$, then $f(\cdot, z) \in B$ and

$$
\|f(\cdot, z)\|_{B}<\|\omega(\cdot, a)\|_{B(R)}+\|f(\cdot, 0)\|_{B}
$$

Let $\rho=a^{-1}\left(\Omega(a)+K\|f(\cdot, 0)\|_{B}\right)<1$. Let $\xi \in F_{o}$ be given arbitrarily. Clearly we have

$$
\|U(\cdot) \xi\|_{C} \leqslant s\|\xi\|<S b=(1-\rho) a
$$

Consider the following sequence of successive approximations in $C$

$$
\begin{aligned}
& z_{1}(t)=\int_{J} G(t, s) f(s, U(s) \xi) d s \\
& z_{n+1}(t)=\int_{J} G(t, s) f\left(s, z_{n}(s)+U(s) \xi\right) d s, \quad n=1,2, \ldots
\end{aligned}
$$

Note that the above integrals exist (since ( $B, C$ ) is admissible, according to Theorem 1), provided that they are all well defined. Indeed, it can be shown (inductively) that

$$
\left\|z_{n}\right\|_{C}<\rho a, \quad n=1,2, \ldots
$$

Now we define a sequence $\left\{r_{n}\right\}$ in $[0,2 a)$ as it follows

$$
\begin{aligned}
& r_{1}=2 \rho a \\
& r_{n+1}=\Omega\left(r_{n}\right), \quad n=1,2, \ldots
\end{aligned}
$$

It is easily seen, using $(\omega 2),(\omega 3)$ and ( $\omega 4$ ) that $\lim _{n \rightarrow \infty} r_{n}=0$.
Moreover, once again by induction it can be shown that

$$
\left\|z_{n+1}-z_{n}\right\|_{C} \leqq r_{n}, \quad n=1,2, \ldots
$$

Therefore, $\left\{z_{n}\right\}$ is a Cauchy sequence in $C$ and there exists $z \in C, z=\lim _{x \rightarrow \infty} z_{n}$. Clearly $\|z\|_{C} \leq \rho$ a. Consequently, the function $x(t ; \xi)=U(t) \xi+z(t)$ would be bounded, since

$$
\|x(\cdot ; \xi)\|_{C}<(1-\rho) a+\rho a=a
$$

and would solve the integral equation

$$
x(t ; \xi)=U(t) \xi+\int_{j} G(t, s) f(s, x(s ; \xi)) d s .
$$

By a simple differentiation it results that $x(\cdot ; \xi)$ is a bounded solution of (3) and

$$
\begin{aligned}
\operatorname{Px}(0 ; \xi) & =P\left(\xi-(I-P) \int_{\mathcal{J}} U^{-1}(s) f(s, x(s ; \xi)) d s\right) \\
& =P \xi=\xi .
\end{aligned}
$$

Furthermore, $x(\cdot ; \xi)$ is the unique bounded solution of (3) with these properties. Indeed, let $\overline{\mathrm{x}}(\cdot ; \xi)$ be another bounded solution of (3) such that $\|\bar{X}(\cdot ; \xi)\|_{C}<a$ aid $P \bar{x}(0 ; \xi)=\xi$
and let $u(t)=\vartheta(x(t ; \xi)-\bar{x}(t ; \xi))$ for some fixed $\vartheta \in(0,1)$. Clearly $u$ would solve the following integral equation

$$
u(t)=\vartheta \int_{J} G(t, s)\{f(s, x(s ; \xi))-f(s, \vartheta x(s ; \xi)-u(s))\} d s .
$$

We define a sequence $\left\{\bar{r}_{n}\right\}$ in $[0,2 a)$ by $\bar{r}_{1}=2 v a, \bar{r}_{n+1}=$ $=\vartheta \Omega\left(\bar{r}_{n}\right), n=1,2, \ldots$. Clearly $\lim _{n \rightarrow \infty} \bar{r}_{n}=0$. It is easily seen by induction that $\|u\|_{C} \leqq \bar{r}_{n}, n=1,2, \ldots$, which implies $\mathrm{u}=0$.

Let $\varepsilon>0$ be arbitrarily fixed ( $\varepsilon<a$ ). If $f(\cdot, 0)=0$, we remark that what we have already shown implies that, for any $\xi \in E_{0},\|\xi\|<S^{-1}(\varepsilon-\Omega(\varepsilon))$, there exists a unique bounded solution $x(\cdot ; \xi)$ of (3) such that $\|x(\cdot ; \xi)\|_{C}<\varepsilon$ and $\operatorname{Px}(0 ; \xi)=\xi$.

Thus for any $\varepsilon>0$ we put $\delta=S^{-1}(\varepsilon-\Omega(\varepsilon))$. Then for any $\xi, \eta \in E_{o}$ such that $\|\xi-\eta\| \leq \delta^{\prime}$ the function $u(t)=$ $=x(t ; \xi)-x(t ; \eta)$ is a bounded solution of

$$
u^{\prime}=A(t) u+g(t, u),
$$

where $g(t, u)=f(t, x(t ; \xi))-f(t, x(t ; \xi)-u)$ satisfies (4) and $g(\cdot, 0)=0$. Since $\|P u(0)\|<\delta$ the above remark implies that $\|u\|_{C}<\varepsilon$, i.e.

$$
\|x(0 ; \xi)-x(0 ; \eta)\| \leqq\|x(\cdot, \xi)-x(\cdot ; \eta)\|_{C}<\varepsilon,
$$

which shows the continuity of the mapping $\xi \mapsto x(0 ; \xi)$ of $F_{0}$ into itself.

Finally, the mapping $H$ defined by

$$
H(\xi)=x(0 ; P \xi)+(I-P) \xi,
$$

with the inverse

$$
H^{-1}(\xi)=\xi-(I-P) x(0 ; P \xi),
$$

extends the mapping $\xi \mapsto x(0 ; \xi)$ to a l-1 mapping of $F_{0}+$ $+E_{1}$ onto itself which le aves the affine subspace $\xi+\mathbb{E}_{1}$ invariant and both it and its inverse are continuous. Therefore, it is a homeomorphism.

Remark 2. Theorem 3 is a generalization of the results of Massera-Schäffer [3] for $\omega(t, r)=\gamma(t) r, \gamma \in B(R)$, $K\|\gamma\|_{B(R)}<1$, and of Szufla [6] for $\omega(t, r)=\gamma(t) \phi(r), \phi(r)$ nondecreasing, $\phi(r)<r, \gamma \in B(R), K\|\gamma\|_{B(R)}<1$.

Given any subinterval $I$ of $J$, we denote by $\chi_{I}$ the characteristic function of $I$, i.e. $\chi_{I}(t)=1$ for $t \in I$ and $\chi_{I}(t)=$ $=0$ for $t \in J \backslash I$. A function Banach space $B$ is called lean (cf. [4], p. 48) if for any $b \in R$

$$
\lim _{t \rightarrow \infty}\left\|x_{[t, \infty)}^{b}\right\|_{B}=0
$$

Theorem 4. Let ( $B, C$ ) be admissible and $f, \omega$ satisfy (f1),(f2), ( $\omega 1$ ) $-(\omega 4),(4)$ and (5). If $B$ is lean and $B$ is not stronger than $L^{l}$, then for every bounded solution $x$ of (3)

$$
\lim _{t \rightarrow \infty}\|x(t)\|=0 .
$$

Proof. Theorem 3 guarantees the existence of bounded solutions of (3). We claim that if $x$ is any bounded solution of (3), then $x$ should solve the integral equation

$$
\begin{equation*}
x(t)=U(t) P x(0)+\int_{J} G(t, s) f(s, x(s)) d s . \tag{6}
\end{equation*}
$$

Indeed, writing $y(t)=x(t)-U(t) P x(0)-\int_{J} G(t, s) P(s$, $x(s)) d s$, it is easy to see that $y$ is a bounded solution of (1) such that

$$
y(0)=x(0)-P x(0)+(I-P) \int_{J} U^{-1}(s) f(s, x(s)) d s,
$$

i.e. $y(0) \in E_{1}$. Therefore, $y=0$, which proves our claim.

Since $B$ is lean and $f(\cdot, x) \in B$ (as it has been shown in the proof of Theorem 3), there exists a $\tau_{0} \in J$, so that for any $\varepsilon>0$ arbitrarily fixed
$\left\|x_{[t, \infty)} f(\cdot, x)\right\|_{B}<\varepsilon / 2 K$, for $t \geqq \tau_{0}$.
On the other hand, the assumption that $B$ is not stronger than $L^{1}$ implies according to Theorem 62.D of [4] that there exist a positive valued function $N$ defined on $J$ and a positive constant $\nu$ such that every solution $y$ of (I) with $y(0) \in E_{0}$ satisfies, for all $t \geqq t_{0} \geq 0$,
$\|y(t)\| \leqslant N\left(t_{0}\right) e^{-\nu\left(t-t_{0}\right)}\left\|y\left(t_{0}\right)\right\|$
and the fundamental solution $U$ of (1) satisfies

$$
\|U(t) P\| \leqslant N(0) e^{-\nu t}, \text { for all } t \in J
$$

i.e.

$$
\lim _{t \rightarrow \infty}\|U(t) P\|=0
$$

Therefore, there exists a $\tau_{1} \in J$ so that
$\|U(t) P\|<\frac{\varepsilon}{2}\left\{\|x(0)\|+\int_{0}^{\tau_{0}}\left\|U^{-1}(s) f(s, x(s))\right\| d s\right\}^{-1}$ for $t \geqq \tau_{1}$.
Consequently, (6) implies, for all $t \geqq \max \left\{\tau_{0}, \tau_{1}\right\}$,
$\|x(t)\| \leqq\|U(t) P\|\|x(0)\|+\| \int_{J} G(t, s) \chi_{\left[0, \tau_{0}\right]} f(s, x(s)) d s$
$+\int_{J} G(t, s) \chi_{\left[\tau_{0}, \infty\right)} f(s, x(s)) d s \|$
$\leqslant\|U(t) P\|\|x(0)\|+\|U(t) P\| \int_{0}^{\tau_{o}} \| U^{-1}(s) f(s$, $x(s)) \| d s$

$$
\begin{aligned}
& +\mathrm{K}\left\|\chi_{\left[\tau_{0}, \infty\right)} \mathrm{f}(\cdot, \mathrm{x})\right\|_{\mathrm{B}} \\
& <\frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon
\end{aligned}
$$

i.e. $\lim _{t \rightarrow \infty}\|x(t)\|=0$.

Remark 3. If $B$ is stronger than $L^{l}$, the above theorem holds if it is in addition assumed that $\lim _{t \rightarrow \infty}\|U(t) P\|=0$.

Remark 4. Theorem 4 is a generalization of an analogous result of Coppel [2] for $B=L^{\infty}\left(R^{n}\right), \omega(t, r)=\gamma r, K \gamma<1$.
