## PRERADICALS AND GENERALIZATIONS OF GF-3' MODULES, I Josef JIRASKO

```
Abstract: QF-3 modules (i.e. modules 2 with \(p^{\{Q\}}(E(Q))=0\) ) were studied by various authors (see [2], [10], \{121, [14]). Rings with \(p{ }^{\{R\}}(X)=0\) for every finitely generated submodule \(X\) of \(B\left(R_{R}\right)\) (left \(Q F-3\) rings) were characterized by T. Sumioka [16]. In this paper QF-3" modules are introduced and are chargcterized in terms of preradicals. Some results on \(\mathrm{QF}-3\) modules and rings and preradicals connected with \(\mathrm{QF}-3\) modules are obtained.
Key words: F-hereditary prergdicals, F-cohereditary preradicals, \(\mathrm{QF}-3^{\prime \prime}\) modules, QP-3 rings.
Classification: 16A63, 16A36
```

In the following $R$ stands for an associative ring with unit. The category of all left $R$-modules will be denoted by R-mod.

A preradical $r$ for $R-m o d$ is a subfunctor of the identity functor, i.e. $r$ assigns to each $M \in R-\bmod$ its submodule $r(M)$ such that $f(r(M)) \subseteq r(N)$ for any $f \in \operatorname{Hom}_{R}(M, N)$. A preradical $r$ is said to be

- idempotent if $r(r(M))=r(M)$ for every $M \in R-m o d$,
- a radical if $r(M / r(M))=0$ for every $M \in R-m o d$,
- hereditary if $r(N)=N \cap r(M)$ whenever $N$ is a submodule of $M, M \in R-m o d$,
- cohereditary if $r(M / N)=(r(M)+N) / N$ whenever $N$ is a

## submodule of $M, M \in R-m o d$.

Let $r$ be a preradical. A module $M$ is called

- r-torsion if $r(M)=M$
- r-torsionfree if $r(M)=0$
- r-splitting if $r(M)$ is a direct summand in $M$.

The class of all r-torsion (r-torsionfree) modules will be denoted by $\mathcal{J}_{\mathbf{r}}\left(\mathcal{F}_{\mathbf{r}}\right)$.

We say that a preradical $r$

- has FGSP if every finitely generated module is r-splitting.

The zero functor will be denoted by zer. For a module $Q$ let us define a radical $p^{\{Q\}}$ by $p^{\{Q\}}(M)=\cap$ Ker $f$ where $p$ runs over all $f \in \operatorname{Hom}_{R}(M, Q), M \in R-m o d$.

Let $r, s$ be preradicals. If $r(M) \subseteq s(M)$ for every $M \in R-m o d$ then we write $r \leq s$.

The idempotent core $\bar{r}$ of a preradical $r$ is defined by $\overline{\mathbf{r}}(\mathrm{M})=\Sigma \mathrm{K}$, where K runs over all r-torsion submodules of $M$ and the radical closure $\widetilde{\mathbf{r}}$ by $\widetilde{\mathbf{r}}(\mathbb{M})=\cap \mathrm{L}$, where $L$ runs over all submodules $L$ of $M$ with $M / L \quad r$-torsionfree.

If $\left\{r_{i} ; i \in I\right\}$ is a family of preradicals then $i \in r_{i}$ $\left(\sum_{i \in I} r_{i}\right)$ is a preradical defined by $\left(\bigcap_{i \in I} r_{i}\right)(M)=\bigcap_{i \in I} r_{i}(M)$ $\left(\left(\sum_{i \in I} r_{i}\right)(M)=\sum_{i \in J} r_{i}(M)\right), M \in R-\bmod$.

The Jacobsen radical will be denoted by $J$ and the singular preradical by $Z$.

A module $M$ is called finitely embedded if there is a finitely generated module $N$ such that $M$ is a submodule of N.

The injective hull of a module $Q$ will be denoted by $\mathrm{E}(Q)$.

A module $M$ is called nonsingular if $Z(M)=0$. A module $M$ is called $\Pi$-projective if every direct product $\mathbf{w}^{I}$ of copies
of $M$ is projective.
A ring $R$ is called

- left perfect if every left R-module has a projective covar,
- left V-ring if every simple R-module is injective,
- left semiartimian if every nonzero left f-module has nonzero socle.

A preradical $r$ is said to be

- 1-idempotent if $r(M) \in \mathcal{J}_{\mathbf{r}}$ for every finitely generated module $M$,
- 2-idempotent if $r(M) \in \mathcal{T}_{r}$ for every finitely embedded modale M,
- F-hereditary if $r(A)=A \cap r(B)$ whenever $A \subseteq B, B$ finitely generated,
- $F_{1}$-hereditary if $r(Q)=0$ implies $r(X)=0$ for every finitely generated submodule $X$ of $E(Q)$,
- F-cohereditary if for every module $M \quad r(M)=\Sigma r(X)$, where $X$ runs over all finitely generated submodales of $M$. For a preradical $r$ let us define preradicals (Fh)(r) and (Fch)(r) as follows:
$(F h)(r)(Q)=r(Q)+\sum(Q \cap r(X))$, where $X$ runs over all Pinitely generated submodules of $E(Q), Q \in R-m o d$, $(F C h)(r)(Q)=\sum r(X)$, where $X$ runs over all finitely generated submodules of $Q, Q \in R-m o d$.

Proposition 1.
(i) Every F-hereditary preradical is F $\mathcal{I}_{1}$-hereditary.
(ii) Every $F_{1}$-hereditary radical is F-hereditary.
(iii) ( Fh ) (r) is an $\mathrm{F}_{1}$-hereditary preradical and $r \leqslant(F h)(r)$.
(iv) If $r \leqslant s$, s F-hereditary then (Fh) (r) $\leqslant$.
(v) (Fh)(r)(Q) does not depend on particular choice of $E(Q)$. ( $\nabla 1$ ) $(F h)(r)$ is the least F-hereditary radical containing $r$.
(vii) (Fch)(r) is an P-cohereditary prergaical and $(f C h)(r) \leqslant r$.
(viii) If $s \leq r, s \quad$-cohereditary then $s \leq(F c h)(r)$.
(ix) (Fch)(r) is the largest $F$-cohereditary preradical contained in $F$.
(x) $(f(f)(r)(Q)=r(Q)$ for every finitely generated module Q.
( xi ) $(F h)(r)(Q)=r(Q)$ for every infective module $Q$.
(xii) Every hereditary and every cohereditary preradical is F-cohereditary.
(xiii) If $\left\{r_{i} ; i \in I\right\}$ is a family of $F$-hereditary preradicals then $\hat{i}_{\varepsilon I} r_{i}$ is $F$-hereditary.
(xiv) If $r$ is a preradical then $\cap\{s ; r \doteq s, s$ F-hereditary (pre)radical\} is the least $P$-hereditary (pre)radical containing $r$.
(xv) If $\left\{r_{i} ; i \in I\right\}$ is a family of $f$-cohereditary preradicals then $\sum_{i} \sum_{i}$ is F-cohereditary.
(xvi) If $r$ is a preradical then $\sum\{s ; s=r, s f$-cohereditary (idempotent) preradical\} is the largest F-cohereditary (idempotent) preradical contained in $r$.
(xvii) A preradical $r$ is $F_{1}$-hereditary if and only if $\tilde{r}$ is $F_{1}$-hereditary.
(xviii) If $r$ is F-hereditary then $\widetilde{T}$ is so.
( $x i x$ ) If $r$ is $F$-hereditary then $\bar{r}$ is so.
Proof. (1). If $r(Q)=0, X$ is a finitely generated submodule of $E(Q)$ and $r$-hereditary then $0=r(Q \cap X)=r(X) \cap$ $\cap(Q \cap X)=Q \cap r(X)$ and hence $r(X)=0$.
(ii). Let $A \subseteq B, B$ finitely generated and $P$ be ar $P_{1}{ }^{-}$ hereditary radical. Consider the following comatetire diogram

Then $\operatorname{Im} g$ is finitely generated and $(r(B) \cap A) / r(A) \in \mathcal{F}_{r}$ since $r$ is a radical. Hence $\operatorname{Im} g \in \mathcal{F}_{r}$ by the assumption. Now $(r(B) \cap A) / r(A) \subseteq g(r(B / r(A)) \subseteq r(\operatorname{Im} g)=0$ and consequent$\operatorname{ly} r(A)=r(B) \cap A$.

The remaining assertions are clear.
Proposition 2. For a radical $r$ the following are equivalent
(i) $\mathbf{r}$ is l-idempotent (2-idempotent),
(ii) if $0 \rightarrow A \rightarrow B \rightarrow C \longrightarrow 0$ is exact, $B$ finitely genorated (finitely embedded), $A, C \in \mathcal{F}_{r}$ then $B \in \mathcal{F}_{r}$.

Proof. (i) implies (ii). It is easy since for on l-idempotent (2-idempotent) radical and finitely generated (embedded) module $F \quad F \in \mathcal{F}_{r}$ if and only if $\operatorname{Hom}_{R}(T, F)=0$ for every $T \in T_{r}$.
(ii) implies (i). Consider the following exact sequence $0 \longrightarrow \mathbf{r}(B) / \mathbf{r}(\mathbf{r}(B)) \longrightarrow B / r(r(B)) \longrightarrow B / r(B) \longrightarrow 0$, where $B$ is finitely generated (embedded). Now $B / r(r(B)) \in \mathcal{F}_{r}^{r}$ by (ii) and consequently $r(B) \in \tau_{r}$.

Proposition 3. The following are equivalent for a preradical $r$
(i) $r$ is $F$-hereditary,
(ii) $r(A)=A \cap r(B)$ whenever $A \cong B, B$ finitely embedded,
(iii) If $A \xrightarrow{\mathcal{L}} F(B)$ is a monomorphism/A cyclic/and $B$ is Pinitely generated (embedded) then $A \in \mathcal{T}_{p}$,
(iv) a) $r$ is l-idempotent (2-idempotent)
and
b) whenever $A \subseteq B, B \in \mathcal{T}_{\mathbf{r}} / A$ cyclic/, $B$ finitely exbedded then $A \in \mathcal{T}_{r^{*}}$.

Proposition 4. The following are equivalent for a preradical $\mathbf{r}$
(1) $r$ is $F_{1}$-hereditary,
(ii) $r(Q)=0$ implies $r(X)=0$ for every initely embedded submodule $X$ of $E(Q)$.

Proposition 5. Let $r$ be a preradical. Then $r$ is F-hereditary if and only if (Fch)(r) is hereditary.

Proof. Suppose $r$ is F-hereditary and $A \subseteq(P C h)(r)(B)$. Without loss of generality we can assume A is finitely generated. Hence there are finitely generated submodules $X_{i}$, $i \in\{1,2, \ldots, n\}$ of $B$ such that $A \subseteq \sum_{i=1}^{n} r\left(X_{i}\right) \subseteq r\left(\sum_{i=1}^{n} X_{i}\right)$ and consequently $A \in \mathcal{J}^{\prime}(F C h)(r)$ since $r$ is $F$-hereditary and $A$ is finitely generated.

Corollary 6. An F-cohereditary preradical is P-hereditary if and only if it is hereditary.

Proposition 7. Let $r$ be an $F$-hereditary radical. Then there is an injective (Fch)(r)-torsionfree module $Q$ such that $r(N)=p^{\{Q\}}(N)$ for every finitely embedded module $N$.

Prool. By Proposition 5 and [3], Theorem 2.5 there is an injective (Fch)(r)-torsionfree module $Q$ such that $\left(\widetilde{F C h)(r)}=p^{\{Q\}}\right.$. Hence $r(N)=p^{\{Q\}}(N)$ for every finitely ems bedded module N.

Proposition 8. Let $r$ be an F-hereditary prersdical (radical) and $\omega$ is the set of all left ideals I with $R / I \in \mathcal{F}_{r}$. Then
(j) $\omega$ is a (radical) filter.

If $s$ is the hereditary preradical (radical) corresponding to $\omega$ then
(ii) $s(M)=\left\{m \in M ; R m \in \mathcal{J}_{\mathbf{r}}\right\}$,
(iii) $s$ is the largest hereditary preradical (radical) contained in $r$,
(iv) $s=(F c h)(r)$.

A left $R$-module $Q$ is called

- QF-3" if the radical $\mathrm{p}^{\{Q\}}$ is $F$-hereditary,
- i QF-3" if the idempotent radical $\overline{p^{\{Q\}}}$ is F-hereditary.

Proposition 2. Let $Q \in R-m o d$. Then the following are equivalent
(i) $Q$ is $Q F-3^{\prime \prime}$,
(ii) $\mathrm{p}^{\{Q\}}(\mathrm{X})=0$ for every finitely generated (embedded) submodule $X$ of $E(Q)$,
(iii) if $X$ is a finitely generated (embedded) submodule of $E(Q)$ then $X$ is isomorphic to a submodule of a direct product of copies of $Q$,
(iv) (Fch) ( $p\{Q\}$ ) is hereditary,
(v) $p^{\{Q\}}(X)=p^{\{E(Q)\}}(X)$ for every finitely generated (embedded module $X$,
(vi) $(F \operatorname{ch})\left(p^{\{Q\}}\right)=p^{\{E(Q)\}}$.
(vii) $(F C h)\left(p^{\{Q\}}\right)(E(Q))=0$,
(viii) for every finitely generated (embedded) module $X$ $p^{\{E(Q)\}}(X)=0$ implies $p^{\{Q\}}(X)=0$,
(ix) a) $\operatorname{Hom}_{R}(p\{Q\}(X), 2)=0$ for every finitely generated (embedded) module $X$
and
b) if $A \cong B$, 'A cyclic, $B$ finitely embedded and $\operatorname{Hom}_{R}(B, Q)=0$ then $\operatorname{Hom}_{R}(A, Q)=0$,
$(x)$ a) If $O \longrightarrow A \rightarrow B \longrightarrow C \longrightarrow 0$ is exact, $B$ is finitely generated (embedded), $A \in F_{p}\{Q\}$ and $C \equiv F_{p}\{Q\}$ then $B \equiv F_{p}\{Q\}$ and
b) if $A=B$ 'A cyclic/, B finitely embedded and $\operatorname{Hom}_{R}(B, Q)=0$ then $\operatorname{Hom}_{R}(A, Q)=0$, (xi) a) if $0 \rightarrow A \rightarrow B \rightarrow C \rightarrow 0$ is exact, $B$ is finitely generated (embedded), $A \in \mathbb{F}_{p}\{Q\}$ and $C \in \mathcal{F}_{p}\{Q\}$ then $B \in \mathcal{F}_{p}\{Q\}$ and
b) for every finitely embedded module $X$
$\operatorname{Hom}_{R}(X, E(Q))=0$ if and only if $\operatorname{Hom}_{R}(X, Q)=0$, (xii) for every monomorphism $h: A \longrightarrow B$, where $B$ is finitely generated (embedded), for every non-zero homomorphism f:A $\rightarrow$ $\longrightarrow Q$ there are homomorphisms $k: \operatorname{Im} P \longrightarrow Q$ and $g: B \longrightarrow Q$ with $O \neq k \circ f=g \circ h$, (xiii) for every cyclic module $C$, finitely generated (embedded) submodule $X$ of $E(C)$ with $h: C \longrightarrow X$ and every mon-zero homomorphism $f: C \longrightarrow Q$ there are homomorphisms $k: \operatorname{Im} f \longrightarrow \mathbb{Q}$ and $g: X \rightarrow Q$ such that $C+k \circ f=g \circ h$, (xiv) if $A$ is a/cyclic/ submodule of a finitely generated (embedded) module $B$ and $\operatorname{Hom}_{R}(A, Q) \mid O$ then there is a homomorphism $g: B-2$ with $g(A) \neq 0$.
proof. The equivalence of the first eleven conditions follows from Propositions 1 (i), (ii), 2, 3 iv), 4 and 5 .
(ii) implies (xii). Consider the following commutative diagram

where $f \neq 0$ and $B$ is finitely generated. Then $p^{\{Q\}}(\operatorname{Im} p)=0$ by (ii) and hence $0 \neq f(A) \nsubseteq p^{\{Q\}}$ (Im $p$ ). Thus there is a homomorphism $q: \operatorname{Im} p$. $Q$ with $q(f(A))$ | O. Put $k=\left.q\right|_{f(A)}$ and $g=q \cup p$. Then $0 \mid k<f=g \cdot h$.
(xiv) implies (ii). Suppose there is a finitely generated submodule $X$ of $E(2)$ such that $p^{i Q s}(X) \mid 0$. Then $L=$ $=p^{\{Q\}}(X) \| Q+0$. Hence there is a homomorphism $g: X>Q$ with $g(L)+0$ by (xiv), a contradiction.

The rest is clear.
Proposition 10. Let $Q: R-m o d$. Then the following are equivalent
(i) 2 is $i Q F-3^{\circ}$,
(ii) $\operatorname{Hom}_{R}(Y, Q):-$ for every finitely embedded nonzero submodule $Y$ of $F(2)$,
(iii) (Fch) ( $\overline{p^{-Q}}$ ) is hereditary, (iv) $\overline{p^{〔 Q^{2}}}(X)=p \cdot E(2):(X)$ for every finitely generated (embedded) module $X$,
(v) $(\overrightarrow{F C h})\left(\overline{p^{-Q}}\right)=p^{\{E(Q)\}}$,
(vi) $(\mathrm{rch})(\overline{\mathrm{p}\{२\}})(\mathrm{L}(\imath))=0$,
(vii) for every finitely generated (embedded) module $X$
$p^{\{E(\hat{Q})\}}(X)=0$ implies $\operatorname{Hom}_{R}(Y, \chi) \neq 0$ whenever $0 \neq Y \subseteq X$,
(viii) if $A \subseteq B / A$ cyclic/, $B$ finitely embedded and
$\operatorname{Hom}_{R}(B, Q)=0$ then $\operatorname{Hom}_{R}(A, Q)=0$,
(ix) for every finitely embedded module $X \operatorname{Hom}_{R}(X, E(Q))=0$ if and only if $\operatorname{Hom}_{R}(X, Q)=0$.

Proof. It follows immediately from Propositions $1(i)$, (ii), 3(iv), 4 and 5 .

Proposition 11. Let $Q \in R-\bmod$. If $p^{\{Q\}}$ has FGSP then $Q$ is $Q F-3^{\prime \prime}$ if and only if $Q$ is $i Q F-3^{\prime \prime}$.

Proof. With respect to Proposition 1 (xix) it suffices to prove the "only if" part. Suppose there is $X \subseteq E(Q), X$ finitely generated and $L=p^{\{Q\}}(X)+0$. Then $\operatorname{Hom}_{R}(L, Q) \neq 0$ by Proposition 10 since 2 is $i Q F-3^{\prime \prime}$. Thus there is a nonzero homomorphism $f: L \longrightarrow Q$ which can be extended to a homomorphism $g: X \rightarrow Q$, a contradiction.

Proposition 12. Let $S$ be a simple R-module. Then $S$ is QF-3" if and only if it is injective.

Proof. Suppose $0 \neq S$ is simple and $Q F-3^{\prime \prime}, O \neq X \subseteq E(S), X$ finitely generated. Then $p^{\{S\}}(x)=0$. Hence $0 \neq S \neq p^{i S\}}(x)$ and consequently there is a homomorphism $f: X \longrightarrow S$ such that $f(S) \neq 0$. Since Ker $f \cap S=0, f$ is an isomorphism. Thus $X=S$. Hence $S=$ $=E(S)$ is injective.

A module $Q$ is said to be an $F$-cogenerator if $p^{\{Q\}}(N)=0$ for every finitely generated (embedded) module $N$.

Remark 13. Let $Q \in R-m o d$. Then $Q$ is an $F$-cogenerator if and only if $(F \mathrm{FCh})\left(\mathrm{p}^{\{Q\}}\right)=z \mathrm{er}$.

Proposition 14. For $Q \in R-m o d$ the following are equivalent
(i) $Q$ is on $F$-cogenerator,
(ii) $Q$ is $Q F-3^{\prime \prime}$ and $E(Q)$ is a cogenerator, (iii) $Q$ is $Q F-3^{\prime \prime}$ and every simple $R$-module is isomorphic to a submodule of $Q$.

Proof. (ii) is equivalent to (iii). By [12], Proposition 2.8. (i) is equivalent to (ii). It follows immediately from Proposition 9.

Corollary 15. Let $Q$ be an injective R-module. Then $Q$ is an $F$-cogenerator if and only if it is a cogenerator.

Proposition 16. Let $Q=\prod_{S \in \mathscr{M}} S$, where $\mathscr{S}$ is the representative set of simple left R -modules. Then the following are equivalent
(i) $Q$ is $Q F-3^{\prime \prime}$,
(ii) $J$ is $F$-hereditary,
(iii) $Q$ is an $F$-cogenerator,
(iv) $R$ is a left $V$-ring.

Proof. (i) is equivalent to (iii). It follows from Proposition 14. The rest is clear since $J=p^{\{Q\}}$.

Proposition 17. The following are equivalent for a faithful module $Q$ :
(i) $(F \mathrm{Fh})\left(\mathrm{p}^{\{Q\}}\right)=\mathrm{Z}$,
(ii) $Q$ is $2 F-3^{\prime \prime}$ and $Z(Q)=0$;
(iii) $\mathcal{F}_{(\text {FCh })\left(p^{\{Q\}}\right)}=\mathcal{F}_{Z}$.

Proof. (iii) implies (ii). As it is easy to see $Z(Q)=$ $=0$. If $X \equiv E(Q), X$ finitely generated then $Z(X)=0$ and consequently $p^{\{Q\}}(X)=0$.
(ii) implies (i). $Z(Q)=0$ implies $Z \leq p^{\{Q\}}$ and hence $\mathrm{Z} \leq(\mathrm{Fch})\left(\mathrm{p}^{\{Q\}}\right)$. On the other hand if N is finitely embedded and $r$-torsion, where $r=p^{\{Q\}}, n \in N$ and $I$ is a left ideal
with $I \cap(0: n)=0$. Then the homomorphism $f: I \rightarrow$ In defined by $f(1)=i n, i \in I$ is an isomorphism. Now $I \in \mathbb{T}_{r}$ since $r$ is F-hereditary. Hence $I \equiv r(R)=0$ by assumption. Thus ( $0: n$ ) is essential in $R$ and consequently $Z(N)=N$. Therefore $r(N) \equiv Z(N)$ for every finitely embedded module $N$ and we have $(F C h)\left(p^{\{Q\}}\right)=Z$.

The rest is clear.
Corollary 18. Let $R$ be a ring with $Z\left(R_{R}\right)=0$. Then the following are equivalent
(i) $R$ is a left $Q F-3^{\prime \prime}$ ring (i.e. $R^{R}$ is $2 F-3^{\prime \prime}$ ), (ii) $(F c h)(p\{R\})=Z$, (iii) $p^{\{R\}}(X)=0$ whenever $X \equiv N, X$ finitely generated and $N$ nonsingular.

Proposition 12. For an T-projective faithful R-module $Q$ the following are equivalent
(i) 2 is $2 r-3^{\prime \prime}$
(ii) for every finitely generated submodule $X$ of $E^{\prime}$ 2) there is a projective module $P_{X}$ such that $X$ is isomorphic to a submodule of $P_{X}$.

Proof. (i) implies (ii). If $X$ is a finitely generated submodule of $\left.E^{\prime} Q\right\rangle$ then $p^{\left\{\sum ?\right.}(X)=0$ and hence $X$ is isomorphic to a subsodule of $Q^{I}$ for some $I$, which is projective.
(ii) implies (i). If $X$ is a finitely generated submodule of $E(Q)$ and $X \doteq P$ for some projective module $P$ then $p^{\{Q\}}(X) \cong p^{\{Q\}}(P)=0$ since $Q$ is faithful.

Corollary 20. Let $R$ be left perfect and right coherent ring. Then the following are equivalent
(i) R is left QF-3",
(ii) for every finitely generated submodule $X$ of $E\left({ }_{R}{ }^{R}\right)$ there is a projective module $P_{X}$ such that $X$ is isomorphic to a submodule of $\mathrm{P}_{\mathrm{X}}$.

## Proposition 21.

(i) Every direct product of $Q F-3^{\circ}$ R-modules is $Q P-3^{\prime \prime}$.
(ii) Every direct sum of $Q F-3^{\prime \prime}$ R-modules is $Q P-3^{\prime \prime}$.
(iii) Every essential extension of a QF-3", R-module is QF-3"。

Proof. (i). Let $Q=\operatorname{T}_{i=1} Q_{i}$, where $Q_{i}$, $i \in I$ are $Q F-3^{\prime \prime}$ modules. Then $\left.p Q^{\{Q\}}=i^{\prime} \in\right\rfloor p^{\left\{Q_{j}\right\}}$ is F-hereditary by Proposition 1 (xiii). Thus $Q$ is $Q P-3^{\circ}$.
(ii). It can be made similarly as in (i).
(iii). Obvious.

Proposition 22. Let $A, B \subset R-m o d$. If $p^{\{A\}}(B)=0$ then the following are equivalent
(i) $A \oplus B$ is $Q F-3^{\prime \prime}$,
(ii) $A$ is $Q F-3^{\circ}$.

Using the method of L. Bican [2], Theorem 11 we obtain the following theorem.

Theorem 23. Let $M$ be a finitely embedded left R-module, $S=\operatorname{Hom}_{R}(M, M)$ and $N \in R-m o d$. If $M_{S}$ is flat and $N$ is QF- $3^{\circ}$ then $\operatorname{Hom}_{R}(M, N)$ is a $Q F-3^{\circ}$ left $S$-module.

Proof. Let us denote $X=\operatorname{Hom}_{R}(M, N)$. If $M_{S}$ is flat then $S^{M^{*}}=\operatorname{Hom}_{R}(M, F(N))$ is injective and consequently $E\left({ }_{S} X\right) \equiv S^{M^{*}}$. Now if $s^{Y}$ is a finitely generated submodule or $E\left({ }_{S} X\right)$ then $S^{Y}=\sum_{i}^{\infty}, S f_{i}$, for some $f_{i} \leqslant S^{M^{*}}, i \equiv\left\{1,2, \ldots, n^{?}\right.$. Further

Im $f_{i}$ is finitely embedjed, $i \in\{1,2, \ldots, n\}$ since $R^{M}$ is finitely embedded and hence $S \equiv \operatorname{Hom}_{R}(M, Z)$, where $Z$ is a finitely generated submadule of $E(N)$. As it is easy to see $p^{\left.i S^{X}\right\}}\left({ }_{S} Y\right) \equiv p^{\left\{S^{X}\right\}}\left(\operatorname{Hom}_{R}(M, Z)\right)=0$ since $p^{i N\}}(Z)=0$ and consequently $S^{X}$ is $Q F-3^{\prime \prime}$.

Corollary 24. Let $R, S$ be Morita equivalent rings via $F=\operatorname{Hom}_{R}(P,-)$. If $R_{R}$ is $Q F-3^{\prime \prime}$ then ${ }_{S} F(Q)$ is $Q F-3^{\prime \prime}$.

Corollary 25. Let $R$ and $S$ be Morita equivalent rings via $F=\operatorname{Hom}_{R}(P,-)$. Then $F$ induces one-to-one correspondence between the isomorphism classes of $Q F-3^{\prime \prime} R$-modules and QF-3" S-modules.

Corollary 26. If $R$ and $S$ are Morita equivalent rings then $R$ is left $Q F-3^{\circ}$ if and only if $S$ is left $Q F-3^{\prime \prime}$.

Proposition 27. Let $Q \in R-m o d$. If every cyclic submodule of $Q$ is $Q F-3^{\prime \prime}$ then $Q$ is $Q P-3^{\prime \prime}$.

Proof. It follows immediately from Proposition 9.
Corollary 28. The following are equivalent
(i) every left $R$-module is $Q P-3^{\prime \prime}$,
(ii) every cyclic left R-module is $2 F-3^{\circ}$.

Proposition 22. Let $R$ be either left or right semiartinian. Then the following assertions are equivalent
(i) every left R-module is $Q F-3^{\prime \prime}$,
(ii) $R$ is a left V-ring,
(iii) every right $R$-module is $Q F-3^{\circ}$,
(iv) $R$ is a right V-ring.

Proof. (i) implies (ii) and (iii) implies (iv). It fol-
lows from Proposition 12. For the rest see [15].
