# GEOMETRY OF LAGRANGEAN STRUCTURES. 1. 

DEMETER KRUPKA

(Received September 9, 1985)

#### Abstract

This paper is the first one of the series intended as a self-contained, relatively complete exposition of differential geometry of Lagrangean structures. It develops the basic differentiation and integration theory of differential odd forms on smooth manifolds and differential odd base forms on smooth fibered manifolds. Except a few minor innovations it does not contain new results.

Key words. Differential form, differential odd form, differential odd base form, exterior product, interior product, pull-back, exterior derivative, integral of differential odd form.

MS Classification. 58 E 99; 58 C 20, 58 C 35.

A Lagrangean structure is a pair $(Y, \lambda)$, where $Y$ is a manifold endowed with the structure of a fibered manifold over an n-dimensional base manifold $X$, and $\lambda$ is an odd base form on some $r$-jet prolongation $J^{r} Y$ of $Y(r \geqq 0)$, horizontal with respect to the projection of $J^{r} Y$ onto $X$ (a lagrangian of order $r$ for $Y$ ). Let $J^{r} \gamma$ denote the $r$-jet prolongation of a section $\gamma$ of $Y$, and let $J^{r} \gamma^{*} \lambda$ denote the pull-back of $\lambda$ by $J \gamma \gamma$. Let $\Omega$ be a compact, $n$-dimensional submanifold of $X$ with boundary. The variational function, or the action function, over $\Omega$, associated with ( $Y, \lambda$ ), is the real-valued function $\gamma \rightarrow \int_{\Omega} J^{r} \gamma^{*} \lambda$, defined on the set of sections of $Y$ over $\Omega$.

The main concern of the theory of Lagrangean structures is to study the variational functions, restricted to prescribed subsets of the set of sections; in particular, one is interested in their critical points and variational differential equations connected with them, extrema, and symmetry properties.

The purpose of the series beginning by this paper is to explain systematically the geometric foundations of the theory of Lagrangean structures, and of the integral variational problems in fibered spaces associated with them. Since the late 1960s, when the first papers on the geometric structure of this class of variational problems (of order 1) appeared, several branches of the subject have developed substantially. Our treatment reflects this development; on the other hand, we also introduce new concepts and ideas, and give original contributions to the theory.

Unless otherwise stated, all manifolds in this work will be real finite-dimensional, $C^{\infty}$-smooth, Hausdorff manifolds with countable base, and all mappings of manifolds will be $C^{\infty}$-smooth.

## 1. ODD BASE FORMS

This introductory part of the work contains the elementary calculus of odd forms on smooth manifolds (Sections 1.1-1.4) and the differentiation theory of odd base forms on smooth fibered manifolds (Sections 1.5-1.6). We emphasize those notions and theorems which will be utilized later in the theory of Lagrangean structures.

The theory of odd forms (covariant, antisymmetric pseudotensor fields) was initiated by de Rham [2] (see also [6]), and has been completed by Bourbaki [1]. The concept of an odd base form was introduced by the author [3] as a field of antisymmetric, covariant geometric objects on a fibered manifold which is "odd" with respect to the base of this fibered manifold only. Our exposition follows the work [4] where this concept is discussed in detail.
1.1. Odd scalars, odd forms. Let $X$ be an $n$-dimensional manifold, $F X$ the bundle of frames over $X$. Let us consider the set of real numbers $R$ as a vector space endowed with the linear representation of the general linear group $G L_{n}(R) \times R \ni$ $\ni(A, s) \rightarrow(\operatorname{sgn} \operatorname{det} A) . s \in R$, where sgn denotes the sign of a real number. The fiber bundle with base $X$ and type fiber $R$, associated with the principal $G L_{n}(R)$ bundle $F X$ by means of this linear representation, is called the bundle of odd scalars over $X$, and is denoted by $R X$. The fiber in $R X$ over a point $x \in X$ is denoted by $R_{x} X$. An equivalence class in $\hat{R}_{x} X$ whose representative is a pair $(\xi, s) \in F X \times R$, is denoted by $[(\xi, s)]$, and is called an odd scalar at the point $x . R X$ is a vector bundle, and $\operatorname{dim} R X=1+\operatorname{dim} X$.

Let $p \geqq 1$ be any integer and let $\Lambda^{p} T^{*} X$ denote the bundle of $p$-forms over $X$. The vector bundle $R X \otimes \wedge^{p} T^{*} X$ is called the bundle odd $p$-form over $X$. The fiber over a point $x \in X$ is the tensor product $R_{x} X \otimes \wedge^{p} T_{x}^{*} X$, where $T_{x}^{*} X=\left(T_{x} X\right)^{*}$ is the dual of tangent vector space $T_{x} X$ at $x$; the points of this fiber are called odd $p$-forms at the point $x$. The bundle $R X$ is also called the bundle of odd 0 -forms, and an odd scalar at a point $x$ is called an odd 0 -form at $x$. A section of the bundle $R X \otimes \wedge^{p} T^{*} X$ defined on an open set $V \subset X$, is called a (differential) odd p-form on $V$; a section of $R X$ defined on $V$ is called a (differential) odd 0 -form on $V$, or a field of odd scalars on $V$.

Convention 1.1. For effective computation with differential forms and differential odd forms we establish the following summation convention. Let $E$ be an $m$-dimensional vector space, $\left(e_{i}\right)$ its basis, $\left(e^{i}\right)$ the dual basis of the dual vector space $E^{*}$. Let $\omega \in \wedge^{p} T^{*} E$ be any element, $p \geqq 1 . \omega$ is uniquely expressible in the form

$$
\begin{equation*}
\omega=\Sigma \omega_{i_{1} \ldots i_{p}} e^{i_{1}} \wedge \ldots \wedge e^{i_{p}} \tag{1.1.1}
\end{equation*}
$$

(summation over all sequences ( $i_{1}, \ldots, i_{p}$ ) such that $1 \leqq i_{1}<\ldots<i_{p} \leqq m$ ), where $\omega_{i_{1} \ldots i_{p}} \in R$ are components of $\omega$ with respect to the basis ( $\mathrm{e}^{i s} \wedge \ldots \wedge e^{i_{p}}$ ).
$1 \leqq i_{1}<\ldots<i_{p} \leqq m$, of the vector space $\wedge^{p} T^{*} E . \omega$ is also uniquely expressible in the form

$$
\begin{equation*}
\omega=\frac{1}{p!} \omega_{j_{1} \ldots j_{p}} e^{j_{1}} \wedge \ldots \wedge e^{j_{p}} \tag{1.1.2}
\end{equation*}
$$

(summation over all $j_{1}, \ldots, j_{p}=1,2, \ldots, m$ ), where the system of coefficients $\omega_{j_{1} \ldots j_{p}}, 1 \leqq j_{1}, \ldots, j_{p} \leqq m$, is antisymmetric in the subscripts; this system extends the system of components of $\omega$ defined by (1.1.1) to all sequences $\left(j_{1}, \ldots, j_{p}\right)$. We shall use both expressions (1.1.1) and (1.1.2) without explicit mentioning the range of summation. In general, when no sign of summation appears, the standard summation convention is applied to the repeated subscripts and superscripts.

Chart expressions. Let $x \in X$ be a point, $(U, \varphi), \varphi=\left(x^{i}\right)$, a chart at $x$. We put

$$
\begin{equation*}
\hat{\varphi}(x)=\left[\left(\left(\left(\frac{\partial}{\partial x^{1}}\right)_{x}, \ldots,\left(\frac{\partial}{\partial x^{n}}\right)_{x}\right), 1\right)\right] . \tag{1.1.3}
\end{equation*}
$$

$\hat{\varphi}(x)$ is an element of $R_{x} X$, called the odd scalar at $x$, associated with the chart $(U, \varphi)$. Since $\operatorname{dim} R_{x} X=1$ and $\hat{\varphi}(x) \neq 0, \hat{\varphi}(x)$ can be taken as a basis of the vector space $\hat{R}_{x} X$. Thus any odd scalar $\hat{s} \in R_{x} X$ has a unique expression of the form

$$
\begin{equation*}
\hat{s}=\sigma_{\varphi} \hat{\varphi}(x) \tag{1.1.4}
\end{equation*}
$$

where $\sigma_{\varphi} \in R$ is the component of $\hat{s}$ with respect to $(U, \varphi)$. The correspondence $x \rightarrow \hat{\varphi}(x)$ is a field of odd scalars on $U$; we call it the field of odd scalars associated with $(\dot{U}, \hat{\varphi})$.

Let $\varrho \in \hat{R}_{x} X \otimes \wedge^{p} T_{x}^{*} X$ be any odd $p$-form at $x, p \geqq 1$. There exists a unique (ordinary) $p$-form $\varrho_{\varphi} \in \wedge^{p} T_{x}^{*} X$ such that

$$
\begin{equation*}
\varrho=\hat{\varphi}(x) \otimes \varrho_{\varphi} \tag{1.1.5}
\end{equation*}
$$

Writing $\varrho_{\varphi}=\Sigma \varrho_{\varphi, i_{1} \ldots i_{p}}\left(\mathrm{~d} x^{i_{1}}\right)_{x} \wedge \ldots \wedge\left(\mathrm{~d} x^{i_{p}}\right)_{x}$ we obtain a unique expression of $\varrho$ in the form

$$
\begin{equation*}
\varrho=\Sigma \varrho_{\varphi, i_{1} \ldots i_{p}} \hat{\varphi}(x) \otimes\left(\mathrm{d} x^{i_{1}}\right)_{x} \wedge \ldots \wedge\left(\mathrm{~d} x^{i_{p}}\right)_{x} \tag{1.1.6}
\end{equation*}
$$

where $\varrho_{\varphi, i_{1} \ldots i_{p}} \in R$ are the components of $\varrho$ with respect to $(U, \varphi)$.
Let $(V, \psi), \psi=\left(y^{j}\right)$, be some other chart at $x$. We easily obtain the following transformation formulas:

$$
\begin{gather*}
\hat{\psi}(x)=\left(\operatorname{sgn} \operatorname{det} D \varphi \psi^{-1}(\psi(x))\right) \hat{\varphi}(x),  \tag{1.1.7}\\
\sigma_{\psi}=\left(\operatorname{sgn} \operatorname{det} D \psi \varphi^{-1}(\varphi(x)) \sigma_{\varphi},\right.  \tag{1.1.8}\\
\varrho_{\psi}=\left(\operatorname{sgn} \operatorname{det} D \psi \varphi^{-1}(\varphi(x))\right) \varrho_{\varphi},  \tag{1.1.9}\\
\varrho_{\psi, j_{1} \ldots j_{p}}=\left(\operatorname{sgn} \operatorname{det} D \psi \varphi^{-1}(\varphi(x))\right) \cdot \frac{\partial x^{i_{1}}}{\partial y^{j_{1}}} \cdots \frac{\partial x^{i_{p}}}{\partial y^{j_{p}}} \varrho_{\varphi, i_{1} \ldots i_{p}} . \tag{1.1.10}
\end{gather*}
$$

In these formulas $D f$ denotes the derivative of a mapping $f$, and the derivatives $\partial x^{i} / \partial y^{j}$ on the right in (1.1.10) are considered at the point $\psi(x)$.

Let $\omega$ be an odd $n$-form on $X(n=\operatorname{dim} X)$. We say that $\omega$ is positive at a point $x \in X$, if there exists a chart $(U, \varphi), \varphi=\left(x^{i}\right)$, at $x$ such that the chart expression

$$
\begin{equation*}
\omega=F_{\varphi} \hat{\varphi} \otimes \mathrm{d} x^{1} \wedge \ldots \wedge \mathrm{~d} x^{n} \tag{1.1.11}
\end{equation*}
$$

satisfies $F_{\varphi}(x)>0$. If $\omega$ is positive at $x$ then for any other chart $(V, \psi)$ at $x F_{\varphi}(x)>$ $>0$; this follows from the transformation formula $F_{\varphi}(x)=\operatorname{det} D \varphi \psi^{-1}(\psi(x))$. An odd $n$-form on $X$, positive at each point, is called a volume element on $X$.

Theorem 1.1. On each manifold there exists a volume element.
Proof. For any chart $(U, \varphi), \varphi=\left(x^{i}\right)$, on $X, \hat{\varphi} \otimes \mathrm{~d} x^{1} \wedge \ldots \wedge \mathrm{~d} x^{n}$ is a volume element on $U$. A volume element on $X$ can be constructed with the help of such volume elements by means of a partition of unity.

An element $\hat{s} \in R_{x} X$ is called a unit odd scalar at $x$ if there exists a chart ( $U, \varphi$ ) at $x$ such that $\hat{s}=\hat{\varphi}(x)$. We shall now give conditions ensuring that the vector bundles $\wedge^{p} T^{*} X$ and $R X \otimes \wedge^{p} T^{*} X, p \geqq 1$, be isomorphic.

Theorem 1.2. Let $X$ be an n-dimensional manifold. The following three conditions are equivalent:
(1) $X$ is orientable.
(2) There exists a field of unit odd scalars defined on $X$.
(3) For each $p \geqq 1$ the vector bundles $\wedge^{p} T^{*} X$ and $R X \otimes \wedge^{p} T^{*} X$ are isomorphic over $i d_{X}$, and the vector bundle $R X$ is isomorphic to $X \times R$ over $i d_{X}$.

Proof. 1. If $X$ is orientable, then there exists an atlas on $X$, formed by charts $\left(U_{i}, \varphi_{i}\right), \varphi_{i}=\left(x_{i}^{i}\right), i \in I$, such that for any $i, x \in I$, det $D \varphi_{i} \varphi_{x}^{-1}>0$. Then according to (1.1.7), $\hat{\varphi}_{i}=\hat{\varphi}_{x}$, and there exists a field of unit odd scalars $\delta$, defined on $X$, such that the restriction of $\delta$ to $U_{t}$ is $\varphi_{i}$.
2. Let $\delta$ be a field of unit odd scalars defined on $X$. For any element $\varrho \in \wedge^{p} T_{x}^{*} X$ we set $v(\varrho)=\delta(x) \otimes \varrho$. Then $v$ defines an isomorphism of the vector bundles $\wedge^{p} T^{*} X$ and $R X \otimes \wedge^{p} T^{*} X$ over $i d_{X}$. The same holds for $\varrho \in X \times R$.
3. Take $p=n$ and suppose that the vector bundles $\wedge^{n} T^{*} X$ and $R X \otimes \wedge^{p} T^{*} X$ are isomorphic over $i d_{X}$. Let $v: \wedge^{p} T^{*} X \rightarrow R X \otimes \wedge^{p} T^{*} X$ be an isomorphism. Let $\omega$ be a volume element on $X$ (Theorem 1.1). Then the mapping $x \rightarrow v^{-1}(\omega(x))$ is an everywhere non-zero (ordinary) $n$-form on $X$, and $X$ must be orientable.

Let $\Omega^{p}(X)$ (resp. $\hat{\Omega}^{p}(X)$ ) denote the module of (ordinary) p-forms (resp. the module of odd $p$-forms) over the ring of functions. Suppose that $X$ is orientable and choose an orientation of $X$, i.e. a maximal atlas ( $U_{i}, \varphi_{i}$ ), $l \in I$, such that for any $t, x \in I$, $\operatorname{det} D \varphi_{i} \varphi_{x}^{-1}>0$ on $U_{i} \cap U_{x}$. By the proof of Lemma 2, relation

$$
\begin{equation*}
\delta=\varphi_{\imath} \tag{1.1.12}
\end{equation*}
$$

defines a field of unit odd scalars on $X$, which is said to be associated with the given orientation. The arising mapping $\Omega^{p}(X) \ni \varrho \rightarrow \delta \otimes \varrho \in \hat{\Omega}^{p}(X)$ is an isomorphism of modules, associated with the orientation.
1.2. Odd base scalars, odd base forms. Recall the definition of the pull-back of a vector bundle. Let $E$ be a vector bundle with base $X$ and projection $\pi: E \rightarrow X$, $f: Y \rightarrow X$ a mapping of manifolds. We set $f^{*} E=\{(y, z) \in Y \times E \mid f(y)=\pi(z)\}$. Let $\pi_{1}$ (resp. $\pi_{2}$ ) be the restriction of the canonical projection $Y \times E \rightarrow Y$ (resp. $Y \times E \rightarrow E$ ) to the set $f^{*} E$. On $f^{*} E$ there exists precisely one structure of a vector bundle with base $Y$ and projection $\pi_{1}$ such that $\pi_{2}: f^{*} E \rightarrow E$ is a homomorphism of vector bundles over $f . f^{*} E$ with this vector bundle structure is called the pullback of the vector bundle $E$ with respect to $f$. The homomorphism $\pi_{2}$ is called canonical.

Let $(W, \chi), \chi=\left(x^{i}, z^{v}\right)$, be a vector bundle chart on $E,(U, \varphi), \varphi=\left(x^{i}\right)$, the associated chart on $X$, and $(V, \psi), \psi=\left(y^{\sigma}\right)$, a chart on $Y$. Suppose that $f(V) \subset U$. Writing for simplicity $y^{\sigma}$ (resp. $z^{v}$ ) instead of $y^{\sigma} \circ \pi_{1}$ (resp. $z^{v} \circ \pi_{2}$ ) we obtain a vector bundle chart $\left(\pi_{1}^{-1}(V), x\right), x=\left(y^{\sigma}, z^{v}\right)$, on $f^{*} E$, which is called associated with the charts $(V, \psi)$ and $(W, \chi)$.

Let $f: Y \rightarrow X$ be a fixed mapping of manifolds. The pull-back $f^{*} R X$ of the bundle of odd scalars $R X$ is called the bundle of odd base scalars over $Y$. An odd base scalar at a point $y \in Y$ is an element of the fiber in $f^{*} R X$ over $y$. A section of $f^{*} R X$, defined on an open subset $V \subset Y$, is called a field of odd base scalars on $V$, or a (differential) odd base 0 -form on $V$.

Let $p \geqq 1$ be any integer. The vector bundle $f^{*} R X \otimes \wedge^{p} T^{*} Y$ is called the bundle of odd base $p$-forms over $Y$. An odd base p-form at a point $y \in Y$ is an element of the fiber in $f^{*} R X \otimes \wedge^{p} T^{*} Y$ over $y$. A section of $f^{*} R X \otimes \wedge^{p} T^{*} Y$, defined on an open subset $V \subset Y$, is called a (differential) odd base p-form on $V$.

Remark 1.1. If $Y=X$ and $f=i d_{X}$ then the notion of an odd base $p$-form ( $p \geqq 0$ ) coincides with the notion of an odd $p$-form.

For any $p, 0 \leqq p \leqq \operatorname{dim} Y$, odd base $p$-forms defined on an open set $V \subset Y$, form a module over the ring of functions; if the mapping $f$ is fixed, this module is denoted by $\hat{\Omega}^{p}(Y)$.

Chart expressions. Let $f: Y \rightarrow X$ be a mapping, $x \in X$ a point, $(U, \varphi)$ a chart at $x, \hat{\varphi}$ the field of odd scalars on $U$, associated with $(U, \varphi)$. We set for each $y \in$ $\in f^{-1}(U)$

$$
\begin{equation*}
f^{*} \hat{\varphi}(y)=(y, \hat{\varphi}(f(y))) . \tag{1.2.1}
\end{equation*}
$$

$f^{*} \hat{\varphi}(y)$ is an odd base scalar at $y$, called the odd base scalar, associated with ( $U, \varphi$ ). Any odd base scalar $\delta$ at $y$ has a unique expression of the form

$$
\begin{equation*}
\delta=\delta_{\varphi} f^{*} \hat{\varphi}(y) \tag{1.2.2}
\end{equation*}
$$

where $\delta_{\varphi} \in R$ is the component of $\delta$ with respect to $(U, \varphi)$. The correspondence $y \rightarrow f^{*} \hat{\varphi}(y)$ is a field of odd base scalars on the open set $f^{-1}(U) \subset Y$; we call it the field of odd base scalars associated with ( $U, \varphi$ ).

Let $y \in f^{-1}(U)$ be any point, $\varrho$ an odd base $p$-form at $y, p \geqq 1$. There exists a unique (ordinary) $p$-form $\varrho_{\varphi} \in \wedge^{p} T_{y}^{*} Y$ such that

$$
\begin{equation*}
\varrho=f^{*} \hat{\varphi}(y) \otimes \varrho_{\varphi} \tag{1.2.3}
\end{equation*}
$$

Let $(V, \chi), \chi=\left(y^{\sigma}\right)$, be a chart at $y$ such that $f(V) \subset U$. Writing $\varrho_{\varphi}=$ $=\Sigma \varrho_{\varphi, \sigma_{1} \ldots \sigma_{\nu}}\left(\mathrm{d} y^{\sigma_{1}}\right)_{y} \wedge \ldots \wedge\left(\mathrm{~d} y^{\sigma_{p}}\right)_{y}$ we obtain a unique expression of $\varrho$ in the form

$$
\begin{equation*}
\varrho=\Sigma \varrho_{\varphi, \chi, \sigma_{1} \ldots \sigma_{p}} f^{*} \hat{\varphi}(y) \otimes\left(\mathrm{d} y^{\sigma_{1}}\right)_{y} \wedge \ldots \wedge\left(\mathrm{~d} y^{\sigma_{p}}\right)_{y} \tag{1.2.4}
\end{equation*}
$$

where $\varrho_{\varphi, \chi, \sigma_{1} \ldots \sigma_{p}} \in R$ are the components of $\varrho$ with respect to $(U, \varphi)$ and $(V, \chi)$.
Let $x \in X$ be a point, $(U, \varphi)$ and $(U, \psi)$ two charts at $x, y \in f^{-1}(U)$ a point, and $(V, \chi), \chi=\left(y^{\sigma}\right),(V, \zeta), \zeta=\left(\bar{y}^{\sigma}\right)$, two charts at $y$. Using the expressions (1.2.1)-(1.2.4) we easily obtain the following transformation formulas:

$$
\begin{equation*}
f^{*} \hat{\psi}(y)=\left(\operatorname{sgn} \operatorname{det} D \varphi \psi^{-1}(\psi(x))\right) f^{*} \hat{\varphi}(y) \tag{1.2.5}
\end{equation*}
$$

$$
\begin{equation*}
\varrho_{\psi, \zeta, v_{1} \ldots v_{p}}=\left(\operatorname{sgn} \operatorname{det} D \psi \varphi^{-1}(\varphi(x))\right) . \frac{\partial y^{\sigma_{1}}}{\partial \bar{y}^{v_{1}}} \ldots \frac{\partial y^{\sigma_{p}}}{\partial \bar{y}^{v_{p}}} . \tag{1.2.7}
\end{equation*}
$$

In (1.2.8), the derivatives $\partial y^{\sigma} / \partial \bar{y}^{\nu}$ are considered at the point $\zeta(y)$.
1.3. Differentiation of odd forms and odd base forms. Let $\chi_{1}, \chi_{2}$ be two $n$-dimensional manifolds, $\alpha: X_{1} \rightarrow X_{2}$ a local diffeomorphism. If $\zeta=\left(\zeta_{1}, \ldots, \zeta_{n}\right)$ is a frame at a point $x \in X_{1}$, then by definition of a local diffeomorphism, $T \alpha \zeta=\left(T \alpha \zeta_{1}, \ldots\right.$, $\left.\ldots, T \alpha \zeta_{n}\right)$ is a frame at $\alpha(x) \in X_{2}$. $\alpha$ induces a homomorphism of vector bundles $R \alpha: R X_{1} \rightarrow R X_{2}$ over $\alpha$ by the formula

$$
\begin{equation*}
R \alpha([(\zeta, s)])=[(T \alpha \zeta, s)] . \tag{1.3.1}
\end{equation*}
$$

$R \alpha$ is obviously a linear isomorphism on each fiber in $R X_{1}$; its restriction to the fiber $R_{x} X_{1}$ is denoted by $R_{x} \alpha$. We have

$$
\begin{equation*}
R i d_{X}=i d_{\hat{\mathbf{R}} \mathbf{X}}, \quad R(\beta \circ \alpha)=R \beta \circ R \alpha \tag{1.3.2}
\end{equation*}
$$

for any $n$-dimensional manifold $X$, and for any two local diffeomorphisms of $n$-dimensional manifolds $\alpha, \beta$ such that $\beta \circ \alpha$ is defined.

Let $\delta$ be a field of odd scalars on $X_{2}$. We put for each $x \in X$

$$
\begin{equation*}
\alpha^{*} \delta(x)=\left(R_{x} \alpha\right)^{-1} \delta(\alpha(x)) \tag{1.3.3}
\end{equation*}
$$

$\alpha^{*} \delta$ is a field of odd scalars on $X_{1}$, called the pull-back of $\delta$ with respect to $\alpha$. Analogously, let $p \geqq 1$, and let $\varrho$ be an odd $p$-form on $X_{2}$. We put for each $x \in X$
and $\xi_{1}, \ldots, \xi_{p} \in T_{x} X_{1}$

$$
\begin{equation*}
\left(\alpha^{*} \varrho\right)(x)\left(\xi_{1}, \ldots, \xi_{p}\right)=\left(R_{x} \alpha\right)^{-1} \varrho(\alpha(x))\left(T \alpha \xi_{1}, \ldots, T \alpha \xi_{p}\right) \tag{1.3.4}
\end{equation*}
$$

$\alpha^{*} \varrho$ is an odd $p$-form on $X_{1}$, called the pull-back of $\varrho$ with respect to $\alpha$.
We shall now generalize the concept of the pull-back to odd base forms. Let $Y_{1}$ (resp. $Y_{2}$ ) be a fibered manifold with base $X_{1}$ (resp. $X_{2}$ ) and projection $\pi_{1}$ (resp. $\pi_{2}$ ). By a homomorphism of fibered manifolds $Y_{1}, Y_{2}$ we shall mean a mapping $\alpha: V \rightarrow Y_{2}$, where $V \subset Y_{1}$ is an open set, such that there exists a mapping $\alpha_{0}: \pi_{1}(V) \rightarrow X_{2}$ satisfying

$$
\begin{equation*}
\pi_{2} \circ \alpha=\alpha_{0} \circ \pi_{1} \tag{1.3.5}
\end{equation*}
$$

Obviously, in this case $\pi_{1}(V) \subset X_{1}$ is open, and $\alpha_{0}$ is unique; we call it the projection of $\alpha$. Unless otherwise mentioned, we take for simplicity $V=Y_{1}$. Suppose, moreover, that $\alpha_{0}$ is a local diffeomorphism. Then $\alpha$ induces a homomorphism of vector bundles, again denoted by $R \alpha: \pi_{1}^{*} R X_{1} \rightarrow \pi_{2}^{*} R X_{2}$, by the formula

$$
\begin{equation*}
R \alpha(y, \delta)=\left(\alpha(y), R \alpha_{0}(\delta)\right) \tag{1.3.6}
\end{equation*}
$$

$R \alpha$ is a linear isomorphism on each fiber, and its projection is $\alpha$; its restriction to the fiber over a point $y \in Y_{1}$ is denoted by $R_{y} \alpha$. We have

$$
\begin{equation*}
\operatorname{Rid}_{Y}=i d_{\pi * \hat{R} X}, \quad R(\beta \circ \alpha)=R \beta \circ R \alpha \tag{1.3.7}
\end{equation*}
$$

for any fibered manifold $Y$ with base $X$ and projection $\pi$, and for any two homomorphisms $\alpha, \beta$ of fibered manifolds whose projections are local diffeomorphisms, such that $\beta \circ \alpha$ is defined.

Let $\delta$ be a field of odd base scalars on $Y_{2}$. We set for each $y \in Y_{1}$

$$
\begin{equation*}
\alpha^{*} \delta(y)=\left(\hat{R}_{y} \alpha\right)^{-1} \delta(\alpha(y)) \tag{1.3.8}
\end{equation*}
$$

$\alpha^{*} \delta$ is a field of odd base scalars on $Y_{1}$, called the pull-back of the field of odd base scalars $\delta$ with respect to the homomorphism $\alpha$. Analogously, let $p \geqq 1$, and let $\varrho$ be an odd base $p$-form on $Y_{2}$. We set for each $y \in Y_{1}$ and $\xi_{1}, \ldots, \xi_{p} \in T_{y} Y_{1}$

$$
\begin{equation*}
\alpha^{*} \varrho(y)\left(\xi_{1}, \ldots, \xi_{p}\right)=\left(R_{y} \alpha\right)^{-1} \varrho(\alpha(y))\left(T \alpha \xi_{1}, \ldots, T \alpha \xi_{p}\right) \tag{1.3.9}
\end{equation*}
$$

$\alpha^{*} \varrho$ is an odd base $p$-form on $Y_{1}$, called the pull-back of the odd base $p$-form $\varrho$ with respect to $\alpha$.

Remark 1.2. If $Y_{1}=X_{1}, \pi_{1}=i d_{X_{1}}, Y_{2}=X_{2}, \pi_{2}=i d_{X_{2}}$, then the pull-back of the corresponding odd base $p$-forms coincides with the pull-back of odd $p$-forms.

Let $Y$ be a fibered manifold with base $X$ and projection $\pi$, let $\gamma: X \rightarrow Y$ be its section, i.e., $\pi \circ \gamma=i d_{X} . \gamma$ can be viewed as a homomorphism of the fibered manifold $X$ with base $X$ and projection $i d_{X}$ into $Y$, whose projection is $i d_{X}$; that is, the pull-back of an odd base $p$-form on $Y$ with respect to $\gamma$ has sense, and is an odd form on $X$. $\pi$ can also be viewed as a homomorphism of fibered manifolds
whose projection is $i d_{x}$; in this case the pull-back of an odd $p$-form on $X$ with respect to $\pi$ is an odd base $p$-form on $Y$.

Remark 1.3. For $\alpha=\pi$ and $\delta=\hat{\varphi}$, definition (1.3.8) reduces to (1.2.1) (see Remark 1).

Chart expressions. Let $y \in Y_{1}$ be a point, $x=\pi_{1}(y)$, and let ( $U_{1}, \varphi_{1}$ ) (resp. $\left(U_{2}, \varphi_{2}\right)$ ) be a chart at $x$ (resp. $\left.\alpha_{0}(x)\right)$ such that $\alpha_{0}\left(U_{1}\right) \subset U_{2}$. Let $\delta$ be a field of odd base scalars on $Y_{2}$. Suppose that

$$
\begin{equation*}
\delta=\delta_{0} \pi_{2}^{*} \hat{\varphi}_{2} \tag{1.3.10}
\end{equation*}
$$

with respect to $\left(U_{2}, \varphi_{2}\right) . \alpha^{*} \delta(y)$ is a unique odd base scalar at $y$ such that $R_{y} \alpha \alpha^{*} \delta(y)=\delta(\alpha(y))$. Since for any odd base scalar $\sigma \in \pi_{1}^{*} R X_{1}$ at $y$

$$
\begin{equation*}
R_{y} \alpha \sigma=\left(\operatorname{sgn} \operatorname{det} D \varphi_{2} \alpha_{0} \varphi_{1}^{-1}\left(\varphi_{1}(x)\right)\right) \sigma_{0} \pi_{2} \hat{\varphi}_{2}(\alpha(y)), \tag{1.3.11}
\end{equation*}
$$

where

$$
\begin{equation*}
\sigma=\sigma_{0} \pi_{1}^{*} \hat{\varphi}_{1}(y) \tag{1.3.12}
\end{equation*}
$$

we have

$$
\begin{equation*}
\alpha^{*} \delta(y)=\left(\operatorname{sgn} \operatorname{det} D \varphi_{1} \alpha_{0}^{-1} \varphi_{2}^{-1}\left(\varphi_{2} \alpha_{0}(x)\right)\right) \delta_{0} \pi_{1}^{*} \hat{\varphi}_{1}(\alpha(y)) \tag{1.3.13}
\end{equation*}
$$

Let $p \geqq 1$, and let $\varrho$ be an odd base $p$-form on $Y_{2}$. Let

$$
\begin{equation*}
\varrho=\pi_{2}^{*} \hat{\varphi}_{2} \otimes \varrho_{\varphi_{2}} \tag{1.3.14}
\end{equation*}
$$

with respect to $\left(U_{2}, \varphi_{2}\right)$. Then

$$
\begin{equation*}
\alpha^{*} \varrho=\alpha^{*} \pi_{2}^{*} \hat{\varphi}_{2} \otimes \alpha^{*} \varrho_{\varphi_{2}} \tag{1.3.15}
\end{equation*}
$$

where $\alpha^{*} \varrho_{\varphi_{2}}$ is the pull-back of (ordinary) p-form.
The mapping $\hat{\Omega}^{p}\left(Y_{2}\right) \ni \varrho \rightarrow \alpha^{*} \varrho \in \hat{\Omega}^{p}\left(Y_{1}\right)$ has the following elementary properties. For any $\varrho_{1}, \varrho_{2} \in \hat{\Omega}^{p}\left(Y_{2}\right)$ and any function $F: Y_{2} \rightarrow R$,

$$
\begin{equation*}
\alpha^{*}\left(\varrho_{1}+\varrho_{2}\right)=\alpha^{*} \varrho_{1}+\alpha^{*} \varrho_{2}, \quad \alpha^{*}\left(F \varrho_{1}\right)=(F \circ \alpha) \alpha^{*} \varrho_{1} . \tag{1.3.16}
\end{equation*}
$$

Moreover, if $\beta: Y \rightarrow Y_{3}$ is a homomorphism of fibered manifolds whose projection is a local diffeomorphism, then for any $\varrho \in \hat{\Omega}^{p}\left(Y_{3}\right)$

$$
\begin{equation*}
\alpha^{*} \beta^{*} \varrho=(\beta \circ \alpha)^{*} \varrho . \tag{1.3.17}
\end{equation*}
$$

Let $Y$ be a fibered manifold with base $X$ and projection $\pi, p \geqq 1, \xi$ a vector field on $Y$. We put for each $y \in Y$ and $\xi_{1}, \ldots, \xi_{p-1} \in T_{y} Y$

$$
\begin{equation*}
\left(i_{\xi} \varrho\right)(y)\left(\xi_{1}, \ldots, \xi_{p-1}\right)=\varrho(y)\left(\xi(y), \xi_{1}, \ldots, \xi_{p-1}\right) \tag{1.3.18}
\end{equation*}
$$

$i_{\xi} \varrho$ is an odd base $(p-1)$-form on $Y$, called the inner product of $\varrho$ and $\xi$.
Chart expressions. If $\varrho$ is expressed by

$$
\begin{equation*}
\varrho=\pi^{*} \hat{\varphi} \otimes \varrho_{\varphi} \tag{1.3.19}
\end{equation*}
$$

with respect to a chart $(U, \varphi)$ on $X$, then $i_{\xi} \varrho$ is expressed by

$$
\begin{equation*}
i_{\xi} \varrho=\pi^{*} \hat{\varphi} \otimes i_{\xi} \varrho_{\varphi} \tag{1.3.20}
\end{equation*}
$$

where $i_{\xi} \varrho_{\varphi}$ is the inner product of the (ordinary) $p$-form $\varrho_{\varphi}$ and $\xi$.
For any $\varrho \in \hat{\Omega}^{p}(Y)$, any two vector fields $\xi_{1}, \xi_{2}$ and two functions $f_{1}, f_{2}$ on $Y$,

$$
\begin{gather*}
i_{f_{1} \xi_{1}+f_{2} \xi_{2}} \varrho=f_{1} \cdot i_{\xi_{1}} \varrho+f_{2} \cdot i_{\xi_{2}} \varrho  \tag{1.3.21}\\
i_{\xi_{1}} i_{\xi_{2}} \varrho=-i_{\xi_{2}} i_{\xi_{1} \varrho} \varrho .
\end{gather*}
$$

If $Y_{1}$ (resp. $Y_{2}$ ) is a fibered manifold with base $X_{1}$ (resp. $X_{2}$ ) and projection $\pi_{1}$ (resp. $\pi_{2}$ ) and $\alpha: Y_{1} \rightarrow Y_{2}$ is a homomorphism of fibered manifolds whose projection is a local diffeomorphism, then for any $\varrho \in \hat{\Omega}^{p}\left(Y_{2}\right)$ and any $\pi$-related vector fields $\xi, \zeta$

$$
\begin{equation*}
\alpha^{*} i_{\xi} \varrho=i_{\zeta} \alpha^{*} \varrho . \tag{1.3.22}
\end{equation*}
$$

Let $\varrho \in \hat{\Omega}^{p}(Y)$ be an odd base form. There exists a unique odd base form $\mathrm{d} \varrho \in$ $\in \Omega^{p+1}(Y)$ such that for each chart $(U, \varphi)$ on $X$

$$
\begin{equation*}
\mathrm{d} \varrho=\pi^{*} \hat{\varphi} \otimes \mathrm{~d} \varrho_{\varphi} \tag{1.3.23}
\end{equation*}
$$

where $\varrho_{\varphi}$ is defined by the chart expression (1.3.19), and d $\varrho_{\varphi}$ is the exterior derivative of the (ordinary) $p$-form $\varrho_{\varphi}$. d $\varrho$ is called the exterior derivative of the odd base $p$-form $\varrho$.

The mapping $\varrho \rightarrow \mathrm{d} \varrho$ is $R$-linear and by definition, for each $\varrho(1.3 .23), \mathrm{d}(\mathrm{d} \varrho)=0$. If $\alpha: Y_{1} \rightarrow Y_{2}$ is a homomorphism of fibered manifolds whose projection is a local diffeomorphism, then for any $\varrho \in \hat{\Omega}^{p}\left(Y_{2}\right)$,

$$
\begin{equation*}
\alpha^{*} \mathrm{~d} \varrho=\mathrm{d} \alpha^{*} \varrho . \tag{1.3.24}
\end{equation*}
$$

Let $Y$ be a fibered manifold. An odd base form $\varrho \in \hat{\boldsymbol{\Omega}}^{p}(Y)$ is called closed, if $\mathrm{d} \varrho=0 . \varrho$ is called exact if there exists an odd base form $\eta \in \hat{\Omega}^{p-1}(Y)$ such that $\varrho=\mathrm{d} \eta$. Each exact odd base form is closed; as in the case of ordinary forms, the converse is also valid locally (the Poincaré lemma).

Theorem 1.3. Let $p \geqq 1$ be an integer, $\varrho \in \hat{\Omega}^{p}(Y)$ a closed odd base form. Then each point $y \in Y$ has a neighbourhood $V$ such that there exists an odd base form $\eta \in \hat{\Omega}^{p-1}(V)$ for $\psi$ hich $\varrho=\mathrm{d} \eta$.

Proof. This follows from the Poincaré lemma for (ordinary) forms.
Let $Y$ be a fibered manifold with base $X$ and projection $\pi$. A vector field $\Xi$ on $Y$ is called $\pi$-projectable, if there exists a vector field $\xi$ on $X$ such that

$$
\begin{equation*}
T \pi \Xi=\xi \circ \pi \tag{1.3.25}
\end{equation*}
$$

If $\xi$ exists, it is unique, and is called the $\pi$-projection of $\Xi . \Xi$ is called $\pi$-vertical, if it is $\pi$-projectable and its $\pi$-projection is the zero vector field.

## D. KRUPKA

Let $\Xi$ be a $\pi$-projectable vector field on $Y, \xi$ its $\pi$-projection, $\alpha_{t}^{\Xi}$ (resp. $\alpha_{i}^{\xi}$ ) the local one-parameter group of $\Xi$ (resp. $\xi$ ). Then for any $t \in R$,

$$
\begin{equation*}
\pi \circ \alpha_{t}^{\Sigma}=\alpha_{t}^{\xi} \circ \pi \tag{1.3.26}
\end{equation*}
$$

on the domain of definition of $\alpha_{t}^{\Sigma} ; \alpha_{t}^{\Sigma}$ is therefore a homomorphism of fibered manifolds.

Let $\varrho \in \hat{\Omega}^{p}(Y)$, let $y \in Y$ be a point. There exists a neighbourhood $V$ of $y$ and $\varepsilon>0$ such that for each $t \in(-\varepsilon, \varepsilon), \alpha_{t}^{\Sigma}$ is defined on $V$. Thus $\alpha_{t}^{\Sigma} \varrho^{\circ}$ is defined, and is an odd base $p$-form on $V$. The curve $t \rightarrow\left(\alpha_{t}^{\Sigma}{ }^{2} \varrho(y)\right)$ lies in the fiber over $y$ in $\pi^{*} R X \otimes \wedge^{p} T^{*} X$; hence the derivative of this curve at a point belongs to the same fiber. We set

$$
\begin{equation*}
\partial_{\Xi} \varrho(y)=\left\{\frac{d}{d t} \alpha_{t}^{\Sigma_{*}} \varrho(y)\right\}_{0}, \tag{1.3.27}
\end{equation*}
$$

(the derivative considered at $t=0$ ). The mapping $y \rightarrow \partial_{z} \varrho(y)$ is an odd base $p$-form on $Y$, called the Lie derivative of the odd base $p$-form $\varrho$ with respect to the $\pi$-projectable vector field $\Xi$.

Remark 1.4. The Lie derivative of an odd base $p$-form with respect to a vector field which is not $\pi$-projectable, is not defined.

Chart expressions. Let $(U, \varphi)$ be a chart on $X$ such that $\alpha_{i}^{\xi}$ is defined on $U$ for all sufficiently small $t$. Then $\operatorname{sgn} \operatorname{det} D \varphi \alpha_{t} \varphi^{-1}=1$ and by (1.1.3) and (1.3.15), $\alpha_{t}^{\bar{z}} \varrho=\pi^{*} \hat{\varphi} \otimes \alpha_{t}^{\bar{z}} \varrho_{\varphi}$. This shows that

$$
\begin{equation*}
\partial_{\Xi} \varrho=\pi^{*} \hat{\varphi} \otimes \partial_{\Xi} \varrho_{\varphi}, \tag{1.3.28}
\end{equation*}
$$

where $\partial_{\xi} \varrho_{\varphi}$ is the Lie derivative of (ordinary) $p$-form $\varrho_{\varphi}$ with respect to $\Xi$.
Let $\varrho \in \hat{\Omega}^{p}(Y), a, b \in R$, and let $\Xi$ and $\Theta$ be two $\pi$-projectable vector fields on $Y$. Then the following formulas easily follow from the analogous ones for (ordinary) forms:

$$
\begin{gather*}
\partial_{\Xi} \varrho=i_{\Xi} \mathrm{d} \varrho+\mathrm{d} i_{\Xi} \varrho,  \tag{1.3.29}\\
\partial_{\Xi} \mathrm{d} \varrho=\mathrm{d} \partial_{\Xi} \varrho,  \tag{1.3.30}\\
\partial_{a \Xi+b \Theta} \varrho=a \partial_{\Xi} \varrho+b \partial_{\Theta} \varrho . \tag{1.3.31}
\end{gather*}
$$

Obviously, the mapping $\varrho \rightarrow \partial_{\varepsilon} \varrho$ is $R$-linear.
Let $\omega \in \hat{\Omega}^{p}(Y), \varrho \in \hat{\Omega}^{q}(Y)$. For each $y \in Y$ and $\xi_{1}, \ldots, \xi_{p+q} \in T_{y} Y$ we put

$$
\begin{gather*}
\omega \wedge \varrho(y)\left(\xi_{1}, \ldots, \xi_{p+q}\right)=  \tag{1.3.32}\\
=\Sigma \frac{1}{p!q!} \operatorname{sgn} \sigma . \omega(y)\left(\xi_{\sigma(1)}, \ldots, \xi_{\sigma(p)}\right) \varrho(y)\left(\xi_{\sigma(p+1)}, \ldots, \xi_{\sigma(p+q)}\right), \\
\varrho \wedge \omega(y)\left(\xi_{1}, \ldots, \xi_{p+q}\right)=  \tag{1.3.33}\\
=\Sigma \frac{1}{p!q!} \operatorname{sgn} \sigma \cdot \omega(y)\left(\xi_{\sigma(p+1)}, \ldots, \xi_{\sigma(p+q)}\right) \varrho(y)\left(\xi_{\sigma(1)}, \ldots, \xi_{\sigma(q)}\right)
\end{gather*}
$$

(summation over all permutations $\sigma$ of the set $\{1,2, \ldots, p+q\}$ ). $\omega \wedge \rho$ (resp. $\varrho \wedge \omega$ ) is an odd base $(p+q)$-form on $Y$, called the exterior product of the $p$-form $\omega$ and odd base $q$-form $\varrho$ (resp. odd base $q$-form $\varrho$ and $p$-form $\omega$ ).

Chart expressions. If $(U, \varphi)$ is a chart on $X$ and $\varrho$ is expressed by (1.3.19), then

$$
\begin{equation*}
\omega \wedge \varrho=\pi^{*} \hat{\varphi} \otimes\left(\omega \wedge \varrho_{\varphi}\right), \quad \varrho \wedge \omega=\pi^{*} \hat{\varphi} \otimes\left(\varrho_{\varphi} \wedge \omega\right) \tag{1.3.34}
\end{equation*}
$$

with respect to $(U, \varphi)$.
The mapping $(\omega, \varrho) \rightarrow \omega \wedge \varrho$ is bilinear over the ring of functions. Moreover,

$$
\begin{equation*}
\omega \wedge \varrho=(-1)^{p q} \varrho \wedge \omega \tag{1.3.35}
\end{equation*}
$$

$$
\begin{equation*}
(\eta \wedge \omega) \wedge \varrho=\eta \wedge(\omega \wedge \varrho) \tag{1.3.36}
\end{equation*}
$$

where $\eta \in \Omega^{r}(Y)$ is any element. If $\Xi$ is a $\pi$-projectable vector field on $Y$, we have

$$
\begin{gather*}
i_{\Xi}(\omega \wedge \varrho)=i_{\Xi} \omega \wedge \varrho+(-1)^{p} \omega \wedge i_{\Xi} \varrho  \tag{1.3.37}\\
\partial_{\Xi}(\omega \wedge \varrho)=\partial_{\Xi} \omega \wedge \varrho+\omega \wedge \partial_{\Xi} \varrho \tag{1.3.38}
\end{gather*}
$$

Finally,

$$
\begin{equation*}
\alpha^{*}(\omega \wedge \varrho)=\alpha^{*} \omega \wedge \alpha^{*} \varrho \tag{1.3.39}
\end{equation*}
$$

for any homomorphism of fibered manifolds $\alpha: Y^{\prime} \rightarrow Y$ whose projection is a local diffeomorphism.
1.4. Integration of odd forms. In this section we develop the integration theory of continuous odd $n$-forms on compact $n$-dimensional manifolds with boundary; within this theory, the integration domains need not be orientable.

Let $X$ be a compact $n$-dimensional manifold with boundary $\partial X, \varrho$ a continuous odd $n$-form on $X$. Suppose that there exists a chart ( $U, \varphi$ ), $\varphi=\left(x^{i}\right)$, on $X$ such that the support of $\varrho$ satisfies supp $\varrho \subset U$. Let $\varrho$ be expressed by

$$
\begin{equation*}
\varrho=f . \hat{\varphi} \otimes \mathrm{d} x^{1} \wedge \ldots \wedge \mathrm{~d} x^{n} \tag{1.4.1}
\end{equation*}
$$

with respect to $(U, \varphi)$. We define the integral of $\varrho$ on $X$ by

$$
\begin{equation*}
\int_{X} \varrho=\int f \varphi^{-1} \tag{1.4.2}
\end{equation*}
$$

where the integral on the right is the standard Lebesgue integral on $R^{n}$. Using the change of variables rule and the transformation formula for the components of an odd $n$-form one can easily verify that the number (1.4.2) is independent of the choice of $(U, \varphi)$. Let now $\varrho$ be an arbitrary continuous odd $n$-form on $X,\left(U_{i}, \varphi_{i}\right)$, $i=1,2, \ldots, N$, a finite system of charts such that $X=\cup U_{i}$, and $\left(\chi_{i}\right)$ a partition of unity, subordinate to the covering ( $U_{i}$ ) of $X$. We define the integral of $\varrho$ on $X$ by

$$
\begin{equation*}
\int_{X} e=\sum_{i} \int_{X} x_{i} e \tag{1.4.3}
\end{equation*}
$$

where each of the summands on the right is given by (1.4.2).

Theorem 1.4. Let $\alpha: X \rightarrow Y$ be a diffeomorphism of compact $n$-dimensional manifolds with boundary, $\varrho$ a continuous odd $n$-form on $Y$. Then

$$
\begin{equation*}
\int_{Y} \varrho=\int_{X} \alpha^{*} \varrho . \tag{1.4.4}
\end{equation*}
$$

Proof. 1. Suppose first that supp $\varrho \subset V$, where $(V, \psi), \psi=\left(y^{j}\right)$, is a chart on $Y$. Then $(U, \varphi), \varphi=\left(x^{j}\right)$, where $\varphi=\psi \alpha$ and $U=\psi^{-1}(V)$, is a chart on $X$. If $\varrho$ has an expression $\varrho=f . \hat{\psi} \otimes \mathrm{d} y^{1} \wedge \ldots \wedge \mathrm{~d} y^{n}$, then $\alpha^{*} \varrho=(f \circ \alpha) . \hat{\varphi} \otimes$ $\otimes \mathrm{d} x^{1} \wedge \ldots \mathrm{~d} x^{n}$, and (1.4.2) gives (1.4.4).
2. Let $\left(V_{i}, \psi_{i}\right)$ be a finite system of charts on $Y$ such that $\cup V_{i}=Y$, and let $\left(\chi_{i}\right)$ be a partition of unity, subordinate to the covering $\left(V_{i}\right)$ of $Y$. Then $\left(U_{i}, \varphi_{i}\right)$, where $U_{i}=\alpha^{-1}\left(V_{i}\right), \varphi_{i}=\psi_{i} \alpha$, is a system of charts on $X$ such that $\left(U_{i}\right)$ is a covering of $X$, and $\left(\chi_{i} \alpha\right)$ is a partition of unity subordinate to this covering. Since $\left(\chi_{i} \alpha\right) \cdot \alpha^{*} \varrho=\alpha^{*}\left(\chi_{i} \varrho\right)$, we get from the definition

$$
\begin{equation*}
\int_{X} \alpha^{*} \varrho=\sum_{i} \int_{X} \alpha^{*}\left(\chi_{i} \varrho\right), \tag{1.4.5}
\end{equation*}
$$

and apply the first part of the proof to each summand on the right.
Let $I \subset R$ be an open interval. A one-parameter system ( $\varrho_{t}$ ), $t \in I$, of odd $n$-forms, defined on an $n$-dimensional manifold with boundary $X$, is called differentiable, if there exists a volume element $\omega$ on $X$ (see Sec. 1.1) such that the function $(t, x) \rightarrow f(t, x)$, defined by the formula

$$
\begin{equation*}
\varrho_{t}(x)=f(t, x) \cdot \omega(x) \tag{1.4.6}
\end{equation*}
$$

is differentiable. If $\left(\varrho_{\boldsymbol{t}}\right)$ is differentiable, we set

$$
\begin{equation*}
\frac{d}{d t} \varrho_{t}=\frac{\partial f}{\partial t} . \omega \tag{1.4.7}
\end{equation*}
$$

( $\mathrm{d} \varrho_{t} / \mathrm{d} t$ ) is a one-parameter system of odd $n$-forms on $X$, called the derivative of $\left(\varrho_{t}\right)$ (with respect to the parameter).

Theorem 1.5. Let $\left(\varrho_{t}\right)$ be a differentiable system of odd n-forms on a compact $n$-dimensional manifold $X$. Then the function $t \rightarrow \int_{X} \varrho_{t}$ is differentiable, and

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} t} \int_{X} \varrho_{t}=\int_{X} \frac{\mathrm{~d}}{\mathrm{~d} t} \varrho_{t} . \tag{1.4.8}
\end{equation*}
$$

Proof. Let us apply the definition (1.4.3) to any element $\varrho_{t}$ of the system ( $\varrho_{t}$ ) We get

$$
\begin{equation*}
\int_{X} \varrho_{t}=\sum_{i} \int_{X} \chi_{i} \varrho_{t} \tag{1.4.9}
\end{equation*}
$$

Write $\varrho_{t}=f_{t} \cdot F_{i} \cdot \hat{\varphi}_{i} \otimes \mathrm{~d} x_{i}^{1} \wedge \ldots \wedge \mathrm{~d} x_{i}^{n}$ with respect to $\left(U_{i}, \varphi_{i}\right), \varphi_{i}=\left(x_{i}^{k}\right)$, where $\omega=F_{i} \cdot \hat{\varphi}_{i} \otimes \mathrm{~d} x_{i}^{1} \wedge \ldots \wedge \mathrm{~d} x_{i}^{n}$ is some volume element. Then

$$
\begin{equation*}
\int_{X} \chi_{i} \rho_{t}=\int \chi_{i} \varphi_{i}^{-1} f_{t} \varphi_{i}^{-1} F_{i} \varphi_{i}^{-1} \tag{1.4.10}
\end{equation*}
$$

Since the mapping $\left(t, x^{\prime}\right) \rightarrow \chi_{i} \varphi_{i}^{-1}\left(x^{\prime}\right) \cdot f_{t} \varphi_{i}^{-1}\left(x^{\prime}\right) . F_{i} \varphi_{i}^{-1}\left(x^{\prime}\right)$ is differentiable, the function $t \rightarrow \int_{X} \chi_{i} \varrho_{\mathbf{t}}$ is also differentiable, and by the classical Leibniz rule

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} t} \int_{X} \chi_{i} \varrho_{t}=\int \chi_{i} \varphi_{i}^{-1} \frac{\mathrm{~d}}{\mathrm{~d} t} f_{t} \varphi_{i}^{-1} F_{i} \varphi_{i}^{-1}=\int_{X} \chi_{i} \frac{\mathrm{~d}}{d t} \varrho_{t} . \tag{1.4.11}
\end{equation*}
$$

By (1.4.9), $t \rightarrow \int_{X} \varrho_{t}$ is differentiable, and we get (1.4.8).
Let $\varrho$ be an odd ( $n-1$ )-form on $X, x_{0} \in \partial X$ a point, and $(U, \varphi), \varphi=\left(x^{l}\right)$, a chart at $x_{0}$. That is, the set $\varphi(U)$ is open in $R_{(-)}^{n}=\left\{y \in R^{n} \mid y^{1}(y) \leqq 0\right\}$, where $y^{1}, \ldots, y^{n}$ are the canonical coordinates on $R^{n}$, and the set $\varphi(\partial X \cap U)$ is given by the equation $x^{1}(x)=0$. Denote for each $i$

$$
\begin{equation*}
\omega_{i}=(-1)^{i-1} \mathrm{~d} x^{1} \wedge \ldots \wedge \mathrm{~d} x^{i-1} \wedge \mathrm{~d} x^{i+1} \wedge \ldots \wedge \mathrm{~d} x^{n} \tag{1.4.12}
\end{equation*}
$$

Then

$$
\begin{equation*}
\varrho=\hat{\varphi} \otimes \varrho_{\varphi}, \quad \varrho_{\varphi}=\Sigma f^{p} \omega_{p} \tag{1.4.13}
\end{equation*}
$$

with respect to $(U, \varphi)$. Denote by $\left(U_{\partial X}, \varphi_{\partial x}\right)$ the chart on $\partial X$ induced by $(U, \varphi)$. We define

$$
\begin{equation*}
\left.\varrho\right|_{\partial x}=\left.\left.\hat{\varphi}\right|_{\partial X} \otimes \varrho_{\varphi}\right|_{\partial X}=\left.f^{1}\right|_{\partial x} \cdot \hat{\varphi}_{\partial X} \otimes \mathrm{~d} x^{2} \wedge \ldots \wedge \mathrm{~d} x^{n}, \tag{1.4.14}
\end{equation*}
$$

where $\varrho_{\varphi} l_{\partial x}$ means the restriction of the (ordinary) ( $n-1$ )-form $\varrho_{\boldsymbol{\varphi}}$ to $\partial X \cap$ $\cap U .\left.\varrho\right|_{\partial X}$ is an odd $(n-1)$-form on $\partial X \cap U$. It is easily seen that there exists a unique odd $(n-1)$-form $\left.\varrho\right|_{\partial X}$ on $\partial X$ whose restriction to $\partial X \cap U$ is given by (1.4.14), for any $(U, \varphi)$. Let $(V, \psi), \psi=\left(y^{j}\right)$, be another chart at $x_{0}$, and write $\varrho=\hat{\psi} \otimes \Sigma g^{q} \eta_{q}$, where $\eta_{q}=(-1)^{q-1} . \mathrm{d} y^{1} \wedge \ldots \wedge \mathrm{~d} y^{q-1} \wedge \mathrm{~d} y^{q+1} \wedge \ldots \wedge \mathrm{~d} y^{n}$. Then $f^{i}=\left|\operatorname{det} D \psi \varphi^{-1}\right| .\left(\partial x^{i} / \partial y^{j}\right) \cdot g^{j}$. Since by definition, $x^{1}=0=x^{1}\left(0, y^{2}, \ldots, y^{n}\right)$ on $\partial X \cap U \cap V$ and the function $y^{1} \rightarrow x^{1}\left(y^{1}, y_{0}^{2}, \ldots, y_{0}^{n}\right)$, where $\left(y_{0}^{1}, \ldots, y_{0}^{n}\right)=$ $=\psi\left(x_{0}\right)$, is increasing, we have $\left|\partial y^{1} / \partial x^{1}\right| .\left(\partial x^{1} / \partial y^{1}\right)=\operatorname{sgn}\left(\partial y^{1} / \partial x^{1}\right)=1$, and

$$
\begin{equation*}
\left.f^{1}\right|_{\partial X}=\left.\left|\operatorname{det} D \psi_{\partial X} \varphi_{\partial X}^{-1}\right| \cdot g^{1}\right|_{\partial X} \tag{1.4.5}
\end{equation*}
$$

on $\partial X \cap U \cap V$. This formula assures us the existence of $\left.\varrho\right|_{\partial x}$. We call $\left.\varrho\right|_{\partial x}$ the restriction of $\varrho$ to the boundary $\partial X$ of $X$, and denote it simply by $\varrho$.

Remark 1.5. Analogous construction of the restriction can be given for any orientable ( $n-1$ )-dimensional submanifold of $X$ and (ordinary) forms. This construction fails, however, for non-orientable submanifolds.

The following is the Stokes' theorem on integration of exact odd forms on compact manifolds with boundary.

Theorem 1.6. Let $X$ be a compact n-dimensional manifold with boundary, and $\varrho$ a differentiable odd $(n-1)$-form on $X$. Then

## D. KRUPKA

$$
\begin{equation*}
\int_{X} \mathrm{~d} \varrho=\int_{\partial X} \varrho . \tag{1.4.16}
\end{equation*}
$$

Proof. Let $\left(U_{i}, \varphi_{i}\right), \varphi_{i}=\left(x_{i}^{k}\right)$, be a finite system of charts on $X$ such that $X=$ $=\cup U_{i},\left(\chi_{i}\right)$ a partition of unity subordinate to the covering $\left(U_{i}\right)$ of $X$. It is sufficient to show that for each $i$,

$$
\begin{equation*}
\int_{X} \mathrm{~d}\left(\chi_{i} \varrho\right)=\int_{\partial X} \chi_{i} \varrho . \tag{1.4.17}
\end{equation*}
$$

We distinguish two cases.
(a) $U_{i} \cap X=\emptyset$. Then $\int_{\partial X} \chi_{i} \varrho=0$. Writing $\chi_{i} \varrho$ in the form

$$
\begin{equation*}
\chi_{i} \varrho=\hat{\varphi}_{i} \otimes \Sigma f_{i}^{p} \omega_{i, p} \tag{1.4.18}
\end{equation*}
$$

we get $\mathrm{d}\left(\chi_{i} \varrho\right)=\hat{\varphi}_{i} \otimes \Sigma\left(\partial f_{i}^{p} / \partial x_{i}^{p}\right) \cdot \mathrm{d} x_{i}^{1} \wedge \ldots \wedge \mathrm{~d} x_{i}^{n}$. Hence by the Fubini theorem,

$$
\begin{equation*}
\int_{X} \mathrm{~d}\left(\chi_{i} \varrho\right)=\Sigma \int \frac{\partial f_{i}^{p}}{\partial x_{i}^{p}}=0 \tag{1.4.19}
\end{equation*}
$$

since each of the functions $f_{i}^{p}$ has a compact support.
(b) $U_{i} \cap X \neq \emptyset$. We get as above

$$
\begin{equation*}
\int_{X} \mathrm{~d}\left(\chi_{i} \varrho\right)=\Sigma \int \frac{\partial f_{i}^{p}}{\partial x_{i}^{p}}=\int \frac{\partial f_{i}^{1}}{\partial x_{i}^{1}}, \tag{1.4.20}
\end{equation*}
$$

since each of the functions $f_{i}^{p}, p \neq 1$, has a compact support, and we integrate over $(-\infty, \infty)$. We get for the remaining integral in (1.4.20)

$$
\begin{gather*}
\int \frac{\partial f_{i}^{1}}{\partial x_{i}^{1}}=\int_{-\infty}^{\infty} \ldots \int_{-\infty}^{\infty} \int_{-\infty}^{0} \frac{\partial f_{i}^{1}}{\partial x_{i}^{1}}=  \tag{1.4.21}\\
=\int_{-\infty}^{\infty} \ldots \int_{-\infty}^{\infty} f_{i}^{1}\left(0, x_{i}^{2}, \ldots, x_{i}^{n}\right) \mathrm{d} x_{i}^{2} \ldots \mathrm{~d} x_{i}^{n}=\int_{\partial X} \chi_{i} \varrho
\end{gather*}
$$

as required.
Remark 1.6. Let $X$ be a compact orientable $n$-dimensional manifold with boundary, $\delta$ a field of unit odd scalars on $X$. Let $\omega$ be a continuous (ordinary) $n$-form on $X$. We define the integral of $\omega$ on $X$ by

$$
\begin{equation*}
\int_{X} \omega=\int_{X} \delta \otimes \omega \tag{1.4.22}
\end{equation*}
$$

This integral obviously depends on the orientation of $X$. By means of (1.4.22), Theorems 1.4-1.6 are easily reformulated for this case.
