ON TORSION GORENSTEIN INJECTIVE MODULES

Okyeon Yi

ABSTRACT. In this paper, we define Gorenstein injective rings, Gorenstein injective modules and their envelopes. The main topic of this paper is to show that if D is a Gorenstein integral domain and M is a left D-module, then the torsion submodule tGM of Gorenstein injective envelope GM of M is also Gorenstein injective. We can also show that if M is a torsion D-module of a Gorenstein injective integral domain D, then the Gorenstein injective envelope GM of M is torsion.

1. Gorenstein injective modules and envelopes

Definition 1. (Iwanaga [5]) A ring is said to be Gorenstein if it is left and right Noetherian and if it has a finite injective dimension as a module over itself both on the left and on the right. If R is Gorenstein and n = 0 is an upper bound for those two dimensions, then R is said to be n-Gorenstein.

Proposition 1. (Iwanaga [6]) If R is *n*-Gorenstein and if M is a left R-module the followings are equivalent:

- (1) $proj.dim_R M < ;$
- (2) $proj.dim_R M = n;$
- (3) $inj.dim_R M < ;$
- (4) $inj.dim_R M = n;$
- (5) $flat.dim_R M < ;$
- (6) $flat.dim_R M = n$.

Examples of Gorenstein rings :

- (1) /(n) for n = 0 is 0-Gorenstein.
- (2) A Noetherian commutative ring of finite global dimension n is n-Gorenstein.
- (3) If R is n-Gorenstein, then R[x] is (n + 1)-Gorenstein.

¹⁹⁹¹ Mathematics Subject Classification: Primary: 13C12; Secondary: 13C11.

Key words and phrases: Nilpotent, Gorenstein Injective Modules. Received May 13, 1997.

- (4) If R is n-Gorenstein, then for any k = 1, $M_k(R)$ (the k = k matrices over R) is n-Gorenstein.
- (5) If k is a field and $f = k[x_1, \dots, x_n]$, then if f = 0 and f is not a constant, $k[x_1, \dots, x_n]/(f)$ is (n = 1)-Gorenstein.

For any ring R, denotes the class of left R-modules of finite projective dimension.

Definition 2. For a Gorenstein ring R, K is Gorenstein injective if and only if $Ext^{1}(L, K) = 0$ whenever $proj.dimL < \ldots$ Gorenstein injective right R-modules are defined analogously.

Proposition 2. If R is Gorenstein ring, K is a Gorenstein injective left R-module and E K is an injective cover of K, then E K is surjective and is also an -cover of K. Furthermore ker(E K) is Gorenstein injective.

Proof. Proposition 4.3 [4].

Definition 3. If N is a left R-module then a complex

 $E_1 \qquad E_0 \qquad N \qquad 0$

is called an injective resolvent of N if all the E_i 's are injective and if for any injective module E the functor $\operatorname{Hom}(E, \cdot)$ makes the complex exact. We note this is equivalent to $E_0 = N$, $E_1 = ker(E_0 = N)$, and $E_{i+1} = ker(E_i = E_{i-1})$ for i = 1 being injective precovers. If in fact these are all injective covers, we call this a minimal injective resolvent of N and write $E_i = E_i(N)$.

If we consider a minimal injective resolvent and a minimal injective resolution of N, say

(1) $E_1(N) = E_0(N) = N = 0$ $0 = N = E^0(N) = E^1(N)$

then pasting together along N we get a complex

 $E_1(N)$ $E_0(N)$ $E^0(N)$

Definition 4. The complex above is said to be the complete minimal injective resolution of N.

Proposition 3. The left R-module N is Gorenstein injective if and only if

$$0 = Ext_i(Q, N) = Ext^i(Q, N) = \overline{Ext_0}(Q, N) = \overline{Ext^0}(Q, N) ,$$

for all i = 1 and for modules Q which have finite injective or projective dimension.

Proof. This is just the usual dimension shifting argument.

Proposition 4. The left R-module N is Gorenstein injective if and only if the complex

$$E_1(N) = E_0(N) = E^0(N) = E^1(N)$$

is exact and remains exact when $\operatorname{Hom}(E, -)$ is applied to it for any injective module E.

Proof. Since this complex can be used to compute $\overline{Ext}_0(-,N)$, $\overline{Ext}^0(-,N)$, $Ext_i(-,N)$ for i-1 we see that exactness is equivalent to the vanishing of these functors when applied to projective modules. The hypothesis guarantees they vanish when applied to injective modules.

Corollary 1. N is Gorenstein injective if and only if its minimal injective resolvent

$$E_1(N) = E_0(N) = N = 0$$

is exact and if $Ext^i(E, N) = 0$ for all i = 1 and injective left *R*-module *E*.

Proof. This is just a reformation of the preceeding result.

Proposition 5. If $0 \quad A \quad N \quad B \quad 0$ is exact sequence of left *R*-module such that

 $0 \quad Hom(E, A) \quad Hom(E, N) \quad Hom(E, B) \quad 0$

is exact for all injective modules E then if A and B are Gorenstein injective, so is N.

Proof. Use the extended long exact sequence associated with

 $0 \quad A \quad N \quad B \quad 0$.

Definition 5. A left R-module N is said to be reduced if it has no injective submodules other than 0.

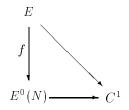

Given a left R-module N, let

$$E_1(N) = E_0(N) = E^0(N) = E^1(N)$$

be its complete minimal injective resolution. Let $C_i = ker(E_i(N) - E_{i-1}(N))$ for $i = 1, C_0 = ker(E_0(N) - E^0(N))$ and $C^i = ker(E^i(N) - E^{i+1}(N))$ for i = 0.

Proposition 6. If N is a reduced, Gorenstein injective left R-module, then the complex is the complete minimal injective resolution of any of the terms C_i and C^i for i = 0. And each C_i and C^i is reduced and Gorenstein injective.

Proof. This is true for $C^0 = N$ by hypothesis. If we can argue that it is true for C_0 and C^1 , then by repeating the argument we can get it true for any of C_i 's and C^i 's. We first argue for C^1 . We have $0 N E^0(N) C^1 0$ is exact. Also $Ext^1(E, N) = 0$ for any injective module E so $E^0(N) C^1$ is an arrow injective precover. If $E C^1$ is an injective submodule, then

can be completed to a commutative diagram. But then $f(E) \bigcap N = 0$, so f(E) = 0and hence E = 0. So C^1 is reduced. If $E^0(N) = C^1$ were not a cover, then $ker(E^0(N) = C^1) = N$ would contain a non-zero injective module, contradicting the fact that N is reduced. Hence () is the complete minimal injective resolution of C^1 . Proposition 4 shows that C^1 is Gorenstein injective. The proof for C_0 is similar.

If f : M N is a linear map then it is easy to see that the following are equivalent:

- (1) f can be factorized through some injective module E;
- (2) f can be factorized by $M = E^0(M)$;
- (3) f can be factorized by $E_0(N) = N$.

Then we have

Corollary 2. If N is a reduced Gorenstein injective left R-module and 0 $K = E_0(N)$ N 0 is exact, then the set of f = End(N) which can be factorized through an injective module form a two-sided ideal of End(N) contained in the jacobson radical of End(N). If A = End(N) is this ideal and B = End(K), is the corresponding ideal for K, then End(N/A) = End(K/B).

Proof. A is clearly a two-sided ideal. Suppose f: N = N can be factorized $N^{-g} E_0(N) \stackrel{\phi}{\to} N$. Then

0	K	$E_0(N)$	N	0
	id	$id + g\phi$	id + f	
0	K	$E_0(N)$	N	0

is commutative. Since $K = E_0(N)$ is an injective envelope, $id + g\phi$ is an isomorphism, and hence so id id + f. We see that any map K = K is part of a commutative diagram

and similarly for any map N = N. It is a simple matter of chasing diagrams to check that this (not one to one) correspondence between maps K = K and maps N = N induces an isomorphism End(K/B) = End(N/A).

Using the notation above we have

Corollary 3. If N is a reduced Gorenstein injective module and $0 N N E^0(N) C = 0$ is exact, then if End(C) is the set of g = End(C) that can be factorized through injective modules then

$$End(N)/A = End(C)/$$

Proof. Similar to that of the above Corollary.

Proposition 7. If 0 A N B 0 is an exact sequence of left *R*-module, then if *A* and *N* are Gorenstein injective then so is *B*. If *N* and *B* are Gorenstein injective, then *A* is Gorenstein injective if and only if $Ext^{1}(E, A) = 0$ for all injective left *R*-modules *E*. If *A* and *B* are Gorenstein injective, then so is *N*.

Proof. For the first claim we note that since A is Gorenstein injective $Ext^1(E, A) = 0$ for all injective module E. Hence

$$0 \quad Hom(E, A) \quad Hom(E, N) \quad Hom(E, B) \quad 0$$

is exact for such E and so we can appeal to the long exact sequence. The proof of the remaining claims is similar.

Corollary 4. If N_1 and N_2 are Gorenstein injective then so is $N_1 = N_2$.

Proposition 8. A reduced Gorenstein injective module N = 0 has infinite injective and projective dimension.

Proof. If any $C^i = 0$ for i = 0, then all the terms of the complete minimal injective resolution of C_i will be 0, hence $C^0 = N$ will be 0. Hence inj. dim N = . Since is a minimal injective resolution of C_i for i = 0, we see that $Ext^{i+1}(N, C_i) = Ext^1(N, C_0)$. Since $0 = C_0 = E_0(N) = N$ 0 doesn't split, $Ext^1(N, C_0) = 0$. So proj. dim N = i + 1 for all i.

Proposition 9. If R is an n-Gorenstein ring and a left R-module K is Gorenstein injective if and only if K is an n-th cosyzygy, i.e., there is an exact sequence

$$0 \qquad M \qquad E^0 \qquad E^1 \qquad \qquad E^n \qquad K \qquad 0$$

of injective resolution of M.

Proof. Given such an exact sequence of modules over the *n*-Gorenstein ring R, let proj. dim $_{R}L < \ldots$ Then by Proposition 1, proj. dim L - n. Hence $Ext^{1}(L, K) = Ext^{n+1}(L, M) = 0$. Hence K is Gorenstein injective. Conversely, suppose K is Gorenstein injective. Let E - K be an injective cover of K. If $\overline{K} = ker(E - K)$ then \overline{K} is Gorenstein injective by Proposition 2. Then if $\overline{E} - \overline{K}$ is an injective cover of \overline{K} , we have the exact sequence $\overline{E} - E - K = 0$. \Box

Proposition 10. If R is a Gorenstein ring, then every left R-module M has a Gorenstein injective envelope GM (or we denote G(M) if it is necessary).

Proof. Theorem 6.1 [4].

2. Torsion Gorenstein injective modules

Definition 6. The torsion submodule tA of a module A is defined by

tA = a A ra = 0 for some non-zero r = R

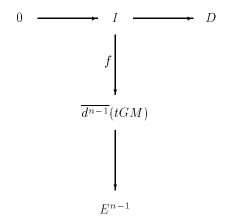

Remark. If R is not a domain, then tA might not be a submodule. If D is an integral domain and M is a torsion D-module, then the injective envelope E(M) of M is torsion.

Theorem 1. If D is a Gorenstein integral domain and M is a left D-module, then the torsion submodule tGM of the Gorenstein injective envelope GM of M is Gorenstein injective.

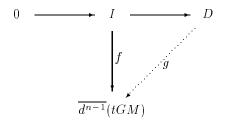

Proof. Since D is integral domain, tGM is a submodule of GM. Since D is Gorenstein, say n-Gorenstein for some n, then by the Proposition 9, GM is an n-th cosyzygy for some N. So there is an exact sequence

$$0 N E^0 E^1 E^{n-1 d^{n-1}} GM 0$$

where E^{i} 's are injective modules. Consider $\overline{d^{n-1}}(tGM) =$ the inverse image of tGM of $d^{n-1} = (d^{n-1})^{-1}(tGM)$. Let *I* be a nonzero ideal of *D* and consider the diagram:

Since E^{n-1} is injective there exists $g: D = E^{n-1}$ such that $g_I = f$. Let x be a nonzero element in I, then $g(x) = f(x) = \overline{d^{n-1}(tGM)}$, i.e., $(d^{n-1}g)(x) = tGM$. So there exists $\alpha = 0$ in D such that $\alpha[(d^{n-1}g)(x)] = \alpha x = [(d^{n-1}g)(1)] = 0$ with $\alpha x = 0$. So $(d^{n-1}g)(1) = tGM$ and $g(1) = \overline{d^{n-1}(tGM)}$. So $g(D) = \overline{d^{n-1}(tGM)}$ since for all $\alpha = D$, $g(\alpha) = \alpha g(1) = tGM$. So

So $\overline{d^{n-1}}(tGM)$ is an injective *D*-module. Now consider the sequence

$$0 N E^{0} E^{1} E^{n-2 d^{n-2}} \overline{d^{n-1}} (tGM)^{d'^{n-1}} tGM 0$$

where $d^{'n-1}$ is a restricted map. Obviously $E^0, E^1, \dots, E^{n-2}, \overline{d^{n-1}}(tGM)$ are injective modules and the sequence is exact at $N, E^0, E^1, \dots, E^{n-2}$, and $\overline{d^{n-1}}(tGM)$. And since imd^{n-2} $kerd^{n-1}$, imd^{n-2} $kerd^{'n-1}$ and if x $ker(d^{'n-1})$, then $d^{n-1}(x) = d^{'n-1}(x) = 0$ tGM. So x $\overline{d^{n-1}}(tGM)$. So the sequence is exact at $d^{n-1}(tGM)$. Hence, by the Propositon 9, tGM is Gorenstein injective. \Box

Theorem 2. If D is a Gorenstein injective integral domain and M is a torsion D-module then the Gorenstein injective envelope GM of M is also torsion.

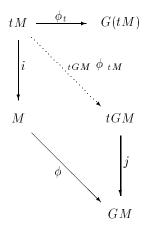

Proof. Consider the diagram:

$$tM \xrightarrow{\phi_t} G(tM)$$

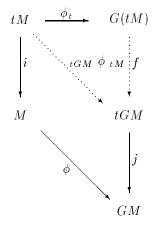

$$\downarrow i$$

$$M \xrightarrow{\phi} GM$$

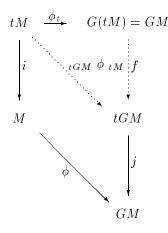

Let x tM. Then there exists a nonzero r D such that rx = 0. Then $r \phi(x) = \phi(rx) = \phi(0) = 0$, so $\phi(x) tGM$ i.e., $\phi i : tM tGM$. So we get

with the bottom parallelogram commutative. Since tGM is Gorenstein injective there exists a map f: G(tM) = tGM such that

the upper triangle is commutative. Since M is torsion tM = M. So G(tM) = G(M) and we get the following diagram.

where j is an inclusion map. Since j = f is an automorphism of GM, j is a surjection. Hence j is an isomorphism between tGM and G(M). Therefore GM = G(M) is torsion.

Theorem 3. Let I be a directed quasi-ordered set. Suppose there are morphisms of direct systems over I

$$A_i, \phi_j^i \stackrel{t}{=} B_i, \psi_j^i \stackrel{s}{=} C_i, \theta_j^i$$

such that

$$0 \qquad A_i \stackrel{t_i}{=} B_i \stackrel{s_i}{=} C_i \qquad 0$$

is exact for each i = I. Then there is an exact sequence of modules

$$0 \qquad \lim_{\to} A_i \stackrel{\overline{i}}{\longrightarrow} \lim_{\to} B_i \stackrel{\overline{s}}{\longrightarrow} \lim_{\to} C_i \qquad 0$$

Proof. We prove that \overline{t} is monic. Assume $x \qquad \lim_{i \to i} A_i$ and $\overline{t}x = 0$ in $\lim_{i \to i} B_i$. Let us set $\lim_{i \to i} A_i = (A_i)/S$ and set $\lambda_i : A_i \qquad A_i$ the i^{th} injection. Let us set $\lim_{i \to i} B_i = (B_i)/T$ and set $\mu_i : B_i \qquad B_i$ the i^{th} injection. Thus, $x = \lambda_i a_i + S$ and $\overline{t}x = \mu_i t_i a_i + T$. Since $\overline{t}x = 0$, there is some $j \qquad i$ with $\psi_j^i t_i a_i = 0$. Since t is a morphism between direct systems, we have $t_j \phi_j^i a_i = 0$. But t_j is monic, whence $\phi_j^i a_i = 0$, and this gives $x = \lambda_i a_i + S = 0$.

Theorem 4. The following are equivalent for a ring R:

- (1) R is left Noetherian,
- (2) every direct limit(directed index set) of injective modules is injective,
- (3) every sum of injective modules is injective.

Proof. Theorem 4.10 [7]

Theorem 5. Let R be an n-Gorenstein ring and (G_i) be a directed system of Gorenstein injective R-modules. Then $\lim_{i \to G_i} G_i$ is Gorenstein injective.

Proof. Since each G_i is Gorenstein injective, there exists an exact sequence ξ_i

 $0 N_i E_i^0 E_i^1 E_i^{n-1} G_i 0.$

This sequence can be constructed functorially. By Theorem 3

 $0 \qquad \lim_{\to} N_i \qquad \lim_{\to} E_i^0 \qquad \qquad \lim_{\to} E_i^{n-1} \qquad \lim_{\to} G_i \qquad 0$

is also exact for each *i*. Since the ring *R* is Gorenstein each $\lim_{\rightarrow} E_i^j$ is injective module by the Theorem 4. So by the Theorem 9 $\lim_{\rightarrow} G_i$ is Gorenstein injective. \Box
