# Comaximal graph of $C(X)$ 

Mehdi Badie

#### Abstract

In this article we study the comaximal graph $\Gamma_{2}^{\prime} C(X)$ of the ring $C(X)$. We have tried to associate the graph properties of $\Gamma_{2}^{\prime} C(X)$, the ring properties of $C(X)$ and the topological properties of $X$. Radius, girth, dominating number and clique number of the $\Gamma_{2}^{\prime} C(X)$ are investigated. We have shown that $2 \leq \operatorname{Rad} \Gamma_{2}^{\prime} C(X) \leq 3$ and if $|X|>2$ then girth $\Gamma_{2}^{\prime} C(X)=3$. We give some topological properties of $X$ equivalent to graph properties of $\Gamma_{2}^{\prime} C(X)$. Finally we have proved that $X$ is an almost $P$-space which does not have isolated points if and only if $C(X)$ is an almost regular ring which does not have any principal maximal ideals if and only if $\operatorname{Rad} \Gamma_{2}^{\prime} C(X)=3$.

Keywords: rings of continuous functions; comaximal graph; radius; girth; dominating number; clique number; zero cellularity; $P$-space; almost $P$-space; connected space; regular ring

Classification: 54C40

## 1. Introduction

Throughout this paper, $G$ stands for an undirected graph. Distance between two vertices $u$ and $v$ is defined as the length of shortest path between $u$ and $v$, and is denoted by $d(u, v)$, then the diameter of $G$ is denoted by $\operatorname{diam}(G)$, and is defined to be the supremum of $\{d(u, v): u, v \in G\}$. If $u$ is a vertex of a graph $G$, then eccentricity of $u$, denoted by $\operatorname{ecc}(u)$, is defined $\max \{d(u, v): v \in G\}$. The set of all vertices with the smallest eccentricity is called center of $G$ and $\min \{\operatorname{ecc}(u): u \in G\}$ is called the radius of $G$ and is denoted by $\operatorname{Rad}(G)$. The minimum length of cycles in a graph $G$ is called the girth of $G$ and is denoted by girth $(G)$. For every $u, v \in G$, let us denote by $\operatorname{gi}(u, v)$ the length of the shortest cycle containing $u$ and $v$. It is clear that girth $(G)=\min \{\operatorname{gi}(u, v): u, v \in G\}$. $G$ is called triangulated (hypertriangulated) if each vertex (edge) of $G$ is a vertex (edge) of a triangle. A subset $A$ of $G$ is called a dominating set if for each $u \in G \backslash A$, there exists $v$ in $A$ such that $u$ is adjacent to $v$. The dominating number of $G$, denoted by $\operatorname{dt}(G)$, is the smallest cardinal number of the form $|A|$, where $A$ is a dominating set of $G$. It is said that two vertices $u$ and $v$ of $G$ are orthogonal, written $u \perp v$, if $u$ and $v$ are adjacent and there is no a vertex $w$ of $G$ which is adjacent to both $u$ and $v$. A graph $G$ is called complemented if for each vertex $u$ of $G$, there is a vertex $v$ of $G$ such that $u \perp v$. A clique of a graph $G$ is defined as
a maximal complete subgraph of $G$ and the supremum of $|A|$, where $A$ is clique of $G$, is called the clique number of $G$, and is denoted by clique $G$.

Let $R$ be a commutative ring with unity. $R$ is called an almost ring if each non-unit element of $R$ is a zero-divisor element of $R$. Comaximal $\operatorname{graph} \Gamma(R)$ is defined as a graph with vertices of elements of $R$, where two distinct vertices $a$ and $b$ are adjacent if and only if $R a+R b=R$. Also consider a subgraph $\Gamma_{2}(R)$ of $\Gamma(R)$ which consists of all non-unit elements of $R$. If $J(R)$ is Jacobson radical of $R$, then $\Gamma_{2}(R) \backslash J(R)$ is denoted by $\Gamma_{2}^{\prime}(R)$.

We assume throughout the paper that $C(X)$ is the ring of all real valued continuous functions on a Tychonoff space $X$. The density (weight) of $X$, denoted by $d(X)(w(X))$, is the infimum of the cardinalities of dense subsets (bases) of $X$. The character of $X$ at a point $p$, denoted by $\chi(p, X)$, is the infimum of the cardinalities of neighborhood bases at $x$ and the character of space $X$, denoted by $\chi(X)$, is the supremum of $\chi(p, X)$, where $p \in X$. A space $X$ is called first (second) countable if $w(X)(\chi(X))$ is countable. The cellularity of $X$, denoted by $c(X)$, is defined by
$\sup \{|\mathcal{U}|: \mathcal{U}$ is a family of mutually disjoint nonempty open subsets of $X\}$.
For any $f \in C(X)$, we denote $f^{-1}\{0\}$ and $X \backslash f^{-1}\{0\}$ by $Z(f)$ and $C o z(f)$, respectively. Every set of the form $Z(f)(\operatorname{Coz}(f))$ is called zeroset (cozeroset). A subset $S$ of $X$ is $C$-embedded in $X$ if for every $f$ in $C(S)$, there exists $g$ in $C(X)$ such that $\left.g\right|_{S}=f$. It is clear that every clopen subset of $X$ is $C$-embedded in $X$. Suppose $p \in \beta X$, then by $M^{p}$ we mean the set $\left\{f \in C(X): p \in \mathrm{cl}_{\beta X} Z(f)\right\}$. By [18, Theorem 7.3 (Gelfand-Kolmogoroff)], $\left\{M^{p}: p \in \beta X\right\}$ is the family of all maximal ideal of $C(X) . X$ is a $P$-space if every prime ideal of $X$ is maximal and we say that $X$ is an almost $P$-space if the interior of every nonempty zeroset of $X$ is nonempty. It is easy to check that $X$ is an almost $P$-space if and only if $C(X)$ is an almost regular ring. By [18, Theorem 14.28], $X$ is a $P$-space if and only if every zeroset of $X$ is open. For more details we refer the reader to [15], [18], [11] and [29].

The study of translating graph properties to algebraic properties is an interesting subject for mathematicians. In [14], linear algebra and some properties of polynomials were used to describe properties of graphs. In [13], the studying of zero-divisor graph of commutative rings has been started. The investigation on zero-divisor graph of commutative rings was then continued in [7], [10], [20], [25], [4], [9], [6], and [8].

In [27], comaximal graph of a commutative ring was defined. On later, in [21], [26], [16], [28], [24], [22], [19], [2], [3], [1], [30], and [23], this investigation was continued.

In [12] and in a section of [5] the zero-divisor graph and the comaximal ideal graph of $C(X)$ were studied, respectively. These investigations tried to associate the ring properties of $C(X)$, the graph properties of graphs on $C(X)$ and the topological properties of $X$.

In this article we study the $\Gamma_{2}^{\prime} C(X)$. Since $J(C(X))=0$, so $\Gamma_{2}^{\prime} C(X)=$ $\Gamma_{2}(C(X))-\{0\}$. If $X$ is singleton, then $\Gamma_{2}^{\prime} C(X)$ is empty. Thus, subsequently we assume $|X|>1$.

By [21, Theorem 3.1, Lemma 3.2 and Proposition 3.3] and [24, Corollary 3.4], we can conclude the following.

Proposition 1.1. For each Tychonoff space $X$,
(a) $\Gamma_{2}^{\prime} C(X)$ is connected;
(b) diam $\Gamma_{2}^{\prime} C(X)=3$;
(c) if $X$ is infinite, then girth $\Gamma_{2}^{\prime} C(X)=3$.

Lemma 1.2. Suppose $f, g \in \Gamma_{2}^{\prime} C(X)$. Then $f$ is adjacent to $g$ if and only if $Z(f) \cap Z(g)=\emptyset$.

Proof: $f$ is not adjacent to $g$ if and only if both $f$ and $g$ are contained in a maximal ideal, that is

$$
\begin{aligned}
\exists p \in \beta X \quad f, g \in M^{p} & \Leftrightarrow \exists p \in \beta X \quad p \in \operatorname{cl}_{\beta X} Z(f) \wedge p \in \operatorname{cl}_{\beta X} Z(g) \\
& \Leftrightarrow \exists p \in \operatorname{cl}_{\beta X} Z(f) \cap \operatorname{cl}_{\beta X} Z(g)=\operatorname{cl}_{\beta X}(Z(f) \cap Z(g)) \\
& \Leftrightarrow Z(f) \cap Z(g) \neq \emptyset
\end{aligned}
$$

In Section 2 we investigate the radius of $\Gamma_{2}^{\prime} C(X)$ and show that $2 \leq \operatorname{Rad} \Gamma_{2}^{\prime} C(X)$ $\leq 3$. The girth of this graph is investigated in Section 3 and we show that if $|X|>$ 2 , then girth $\Gamma_{2}^{\prime} C(X)=3$. In Section 4 we study the dominating number and the clique number of the graph $\Gamma_{2}^{\prime} C(X)$. We prove that $d(X) \leq \mathrm{dt} \Gamma_{2}^{\prime} C(X) \leq w(X)$, introduce zeroset cellularity of $X$ and show that it is equal to clique $\Gamma_{2}^{\prime} C(X)$. In Section 5 we use the notions of the previous sections to associate the topological properties of $X$, the ring properties $C(X)$ and the graph properties of $\Gamma_{2}^{\prime} C(X)$. In this section we observe that $\Gamma_{2}^{\prime} C(X)$ is triangulated (hypertriangulated, complemented) if and only if $X$ does not have any isolated points ( $X$ is connected, $X$ is a $P$-space), and finally we conclude that $X$ is an almost $P$-space which does not have isolated points if and only if $C(X)$ is regular ring which does not have any principal maximal ideals if and only if $\operatorname{Rad} \Gamma_{2}^{\prime} C(X)=3$.

Similar results to Theorem 4.4, Proposition 4.7 and Corollary 4.8 devoted to zero divisor graphs may be found in [12]. Here we prove them for comaximal graphs.

## 2. Radius of the graph

Lemma 2.1. For any $f$ and $g$ in $\Gamma_{2}^{\prime} C(X)$
(a) $d(f, g)=1$ if and only if $Z(f) \cap Z(g)=\emptyset$;
(b) $d(f, g)=2$ if and only if $Z(f) \cap Z(g) \neq \emptyset$ and $Z(f) \cup Z(g) \neq X$;
(c) $d(f, g)=3$ if and only if $Z(f) \cap Z(g) \neq \emptyset$ and $Z(f) \cup Z(g)=X$.

Proof: (a) By Lemma 1.2, it is clear.
(b) $\Rightarrow$ Since $d(f, g)=2, f$ is not adjacent to $g$, thus $Z(f) \cap Z(g) \neq \emptyset$, by Lemma 1.2. We now show that $Z(f) \cup Z(g) \neq X$. Suppose that, on the contrary $Z(f) \cup Z(g)=X$. From $d(f, g)=2$ it follows that $h$ in $\Gamma_{2}^{\prime} C(X)$ exists such that $h$ is adjacent to both $f$ and $g$, hence by Lemma 1.2,

$$
\left\{\begin{array}{l}
Z(h) \cap Z(f)=\emptyset \\
Z(h) \cap Z(g)=\emptyset
\end{array} \quad \Rightarrow \quad Z(h)=Z(h) \cap X=Z(h) \cap[Z(f) \cup Z(g)]=\emptyset\right.
$$

which is a contradiction.
$(\mathrm{b}) \Leftarrow$ Since $Z(f) \cap Z(g) \neq \emptyset, d(f, g)>1$, by Lemma 1.2. Since $Z(f g)=$ $Z(f) \cup Z(g) \neq X, p \in X \backslash Z(f g)$ exists, hence there is some $h$ in $C(X)$ such that $p \in Z(h)$ and $Z(f g) \cap Z(h)=\emptyset$, thus $h \in \Gamma_{2}^{\prime} C(X)$ and

$$
\begin{gathered}
\emptyset=[Z(f) \cup Z(g)] \cap Z(h)=[Z(f) \cap Z(h)] \cup[Z(g) \cap Z(h)] \\
\Rightarrow \quad\left\{\begin{array}{l}
Z(f) \cap Z(h)=\emptyset \\
Z(g) \cap Z(h)=\emptyset
\end{array}\right.
\end{gathered}
$$

Hence $h$ is adjacent to both $f$ and $g$, thus $d(f, g)=2$.
(c) By Proposition 1.1(b), it is clear.

Lemma 2.2. For every $f \in \Gamma_{2}^{\prime} C(X), \operatorname{ecc}(f) \geq 2$.
Proof: Since $Z(f) \cap Z(2 f)=Z(f) \neq \emptyset$ and $Z(f) \cup Z(2 f)=Z(f) \neq X$, $d(f, 2 f)=2$, by Lemma 2.1. This implies that $\operatorname{ecc}(f) \geq 2$.
Proposition 2.3. Suppose $f \in \Gamma_{2}^{\prime} C(X)$. Then $\operatorname{ecc}(f)=2$ if and only if either $\operatorname{int} Z(f)=\emptyset$ or $Z(f)=\{p\}$, in which $p$ is an isolated point.
Proof: $\Rightarrow$ By Lemma 2.2, $d(f, g) \neq 3$, for every $g \in \Gamma_{2}^{\prime} C(X)$. From Lemma 2.1, it follows that

$$
\begin{array}{ll} 
& \forall g \in \Gamma_{2}^{\prime} C(X)
\end{array} \quad Z(f) \cup Z(g) \neq X \vee Z(f) \cap Z(g)=\emptyset \quad\left(\begin{array}{ll}
\prime \\
\equiv & \forall g \in \Gamma_{2}^{\prime} C(X) \\
\equiv & Z(f) \cup Z(g)=X \Rightarrow Z(f) \cap Z(g)=\emptyset  \tag{1}\\
\equiv & \operatorname{Coz}(g) \subseteq Z(f) \Rightarrow Z(f)=\operatorname{Coz}(g)
\end{array}\right.
$$

If $\operatorname{int} Z(f) \neq \emptyset$, then $Z(f)$ is open. It is sufficient to show that $Z(f)$ is singleton. Suppose, on the contrary, there are two distinct points $p$ and $q$ in $Z(f)$, thus there is a function $h: Z(f) \rightarrow \mathbb{R}$, such that $h(p)=0$ and $h(q)=1$. Since $Z(f)$ is clopen, $Z(f)$ is $C$-embedded in $X$, thus $k$ in $C(X)$ exists such that $\left.k\right|_{Z(f)}=h$.

Let $g: X \rightarrow \mathbb{R}$ be given by

$$
g(x)= \begin{cases}1 & x \in Z(f) \\ 0 & x \notin Z(f)\end{cases}
$$

Since $Z(f)$ is clopen, $g \in \Gamma_{2}^{\prime} C(X)$ and therefore $g k \in \Gamma_{2}^{\prime} C(X) . \operatorname{Coz}(g k)=$ $\operatorname{Coz}(g) \cap \operatorname{Coz}(k) \subseteq Z(f)$, but $Z(f) \neq \operatorname{Coz}(g k)$ since $p \in Z(f) \backslash \operatorname{Coz}(g k)$. This contradicts the fact (1).
$\Leftarrow$ By Proposition 1.1, it suffices to prove that

$$
\forall g \in \Gamma_{2}^{\prime} C(X) \quad d(f, g) \neq 3
$$

According to the first part of the proof, the above statement is equivalent to

$$
\forall g \in \Gamma_{2}^{\prime} C(X) \quad \operatorname{Coz}(g) \subseteq Z(f) \Rightarrow Z(f)=\operatorname{Coz}(g)
$$

By the assumption, the above statement is clear.
An immediate conclusion of Proposition 1.1, and Lemma 2.2, is the following corollary.

Corollary 2.4. $2 \leq \operatorname{Rad} \Gamma_{2}^{\prime} C(X) \leq 3$.

## 3. Girth of the graph

Lemma 3.1. Let $f \in \Gamma_{2}^{\prime} C(X)$. Then $\operatorname{Coz}(f)$ is not singleton if and only if $f$ is a vertex of a triangle.

Proof: $\Rightarrow$ Let $p$ and $q$ be distinct elements of $\operatorname{Coz}(f)$. There are two disjoint zerosets $Z_{1}$ and $Z_{2}$ containing $p$ and $q$, respectively. Since $p, q \notin Z(f)$, there are two zerosets $Z_{3}$ and $Z_{4}$ containing $p$ and $q$, respectively, such that $Z_{3} \cap Z(f)=$ $Z_{4} \cap Z(f)=\emptyset$. Put $Z(g)=Z_{3} \cap Z_{1}$ and $Z(h)=Z_{4} \cap Z_{2}$. Consequently, $g, h \in \Gamma_{2}^{\prime} C(X), Z(f) \cap Z(g)=\emptyset, Z(g) \cap Z(h)=\emptyset$ and $Z(h) \cap Z(f)=\emptyset$. Lemma 1.2 now shows that $f$ is adjacent to $g, g$ is adjacent to $h$ and $h$ is adjacent to $f$, thus $f$ is vertex of a triangle.
$\Leftarrow$ There are vertices $g$ and $h$ in $\Gamma_{2}^{\prime} C(X)$ such that $f$ is adjacent to $g, g$ is adjacent to $h$ and $h$ is adjacent to $f$. By Lemma 1.2

$$
\left\{\begin{array} { l } 
{ Z ( f ) \cap Z ( g ) = \emptyset } \\
{ Z ( f ) \cap Z ( h ) = \emptyset } \\
{ Z ( g ) \cap Z ( h ) = \emptyset }
\end{array} \Rightarrow \left\{\begin{array}{l}
\emptyset \neq Z(g) \subseteq \operatorname{Coz}(f) \\
\emptyset \neq Z(h) \subseteq \operatorname{Coz}(f) \\
Z(g) \cap Z(h)=\emptyset
\end{array}\right.\right.
$$

Hence $\operatorname{Coz}(f)$ is not singleton.
Theorem 3.2. If $|X|>2$, then girth $\Gamma_{2}^{\prime} C(X)=3$.
Proof: Since $X$ has some non-singleton cozeroset, girth $\Gamma_{2}^{\prime} C(X)=3$, by Lemma 3.1.

Example 3.3. If $|X|>2$ and finite, then $C(X)$ has finitely many maximal ideal and girth $\Gamma_{2}^{\prime} C(X)=3$, by Theorem 3.2. This is a counterexample to the converse of [24, Corollary 3.4].

## 4. Dominating and clique number

Lemma 4.1. Let $f, g \in \Gamma_{2}^{\prime} C(X)$.
(a) If $Z(f) \cap Z(g)=\emptyset$ and $Z(f) \cup Z(g)=X$, then $\operatorname{gi}(f, g)=4$.
(b) If $Z(f) \cap Z(g)=\emptyset$ and $Z(f) \cup Z(g) \neq X$, then $\operatorname{gi}(f, g)=3$.
(c) If $Z(f) \cap Z(g) \neq \emptyset$ and $Z(f) \cup Z(g) \neq X$, then $\operatorname{gi}(f, g)=4$.
(d) If $Z(f) \cap Z(g) \neq \emptyset$ and $Z(f) \cup Z(g)=X$, then $\operatorname{gi}(f, g)=6$.

Proof: (a) $Z(f) \cap Z(g)=\emptyset, Z(g) \cap Z(2 f)=\emptyset, Z(2 f) \cap Z(2 g)=\emptyset$ and $Z(2 g) \cap$ $Z(f)=\emptyset$. By Lemma 1.2, $f$ is adjacent to $g, g$ is adjacent to $2 f, 2 f$ is adjacent to $2 g$ and $2 g$ is adjacent to $f$, it follows that $\operatorname{gi}(f, g) \leq 4$. We claim that $\operatorname{gi}(f, g) \neq 3$ and therefore $\operatorname{gi}(f, g)=4$. On the contrary, suppose $\operatorname{gi}(f, g)=3$, then $h$ in $\Gamma_{2}^{\prime} C(X)$ exists such that $h$ is adjacent to both $f$ and $g$, by Lemma 1.2

$$
\left\{\begin{array}{l}
Z(h) \cap Z(f)=\emptyset \\
Z(h) \cap Z(g)=\emptyset
\end{array} \quad \Rightarrow \quad Z(h)=Z(h) \cap X=Z(h) \cap[Z(f) \cup Z(g)]=\emptyset\right.
$$

which is impossible.
(b) Suppose $x \in X \backslash[Z(f) \cup Z(g)]$. There is some $h$ in $\Gamma_{2}^{\prime} C(X)$ such that $x \in Z(h)$ and

$$
Z(h) \cap[Z(f) \cup Z(g)]=\emptyset \quad \Rightarrow \quad Z(h) \cap Z(f)=\emptyset \text { and } Z(h) \cap Z(g)=\emptyset
$$

thus $h \in \Gamma_{2}^{\prime} C(X)$ and $h$ is adjacent to both $f$ and $g$, by Lemma 1.2, hence $\operatorname{gi}(f, g)=3$.
(c) Suppose $x \in X \backslash[Z(f) \cup Z(g)]$, then there is some $h \in \Gamma_{2} C(X)$, such that $x \in Z(h)$ and

$$
Z(h) \cap[Z(f) \cup Z(g)]=\emptyset \quad \Rightarrow \quad Z(h) \cap Z(f)=\emptyset \text { and } Z(h) \cap Z(g)=\emptyset
$$

thus $Z(f) \cap Z(2 h)=\emptyset$ and $Z(2 h) \cap Z(g)=\emptyset$. From Lemma 4.1, we deduce that $f$ is adjacent to $h, h$ is adjacent to $g, g$ is adjacent to $2 h$ and $2 h$ is adjacent to $f$, this gives $\operatorname{gi}(f, g) \leq 4$. Since $Z(f) \cap Z(g) \neq \emptyset$, so $f$ is not adjacent to $g$ and therefore $\operatorname{gi}(f, g) \neq 3$, and so $\operatorname{gi}(f, g)=4$.
(d) By Lemma 2.1, $d(f, g)=3$, thus $\operatorname{gi}(f, g) \leq 6$ and there are $h$ and $k$ in $\Gamma_{2}^{\prime} C(X)$ such that $f$ is adjacent to $h, h$ is adjacent to $k$ and $k$ is adjacent to $g$. It is easily seen that $g$ is adjacent to $2 k, 2 k$ is adjacent to $2 h$ and $2 h$ is adjacent to $f$. This clearly forces $\operatorname{gi}(f, g)=6$.

$$
\begin{aligned}
& Z(f) \cap Z(g)=\emptyset \\
& Z(f) \cup Z(g) \neq X \\
& \quad \operatorname{gi}(f, g)=3
\end{aligned}
$$

$$
\begin{aligned}
& Z(f) \cap Z(g)=\emptyset \\
& Z(f) \cup Z(g)=X \\
& \operatorname{gi}(f, g)=4
\end{aligned}
$$

$Z(f) \cap Z(g) \neq \emptyset$
$Z(f) \cup Z(g) \neq X$
$\operatorname{gi}(f, g)=4$

$$
\begin{aligned}
& Z(f) \cap Z(g) \neq \emptyset \\
& Z(f) \cup Z(g)=X \\
& \operatorname{gi}(f, g)=6
\end{aligned}
$$

Corollary 4.2. (a) Every cycle in $\Gamma_{2}^{\prime} C(X)$ has length 3 or 4.
(b) Every edge of $\Gamma_{2}^{\prime} C(X)$ is edge of a cycle with length 3 or 4.
(c) Every vertex of $\Gamma_{2}^{\prime} C(X)$ is vertex of a square.

Proof: (a) and (b) are immediate conclusions of Lemma 4.1.
(c) For each $f \in \Gamma_{2}^{\prime} C(X)$, we have

$$
\left\{\begin{array}{l}
Z(f) \cap Z(2 f) \neq \emptyset \\
Z(f) \cup Z(2 f) \neq X .
\end{array}\right.
$$

By Lemma 4.1, gi $(f, 2 f)=4$, and therefore $f$ is vertex of a square.
Lemma 4.3. If $X$ is an infinite space, then every dominating set of $\Gamma_{2}^{\prime} C(X)$ is infinite.

Proof: We show that none of the finite subsets of $\Gamma_{2}^{\prime} C(X)$ is a dominating set. Suppose $A=\left\{f_{1}, f_{2}, \ldots, f_{n}\right\}$ is a finite subset of $\Gamma_{2}^{\prime} C(X)$. Each $Z\left(f_{i}\right)$ is nonempty, thus $p_{i}$ in $Z\left(f_{i}\right)$ exists. Since $X$ is infinite, $p_{0}$ in $X$ distinct from $p_{i}$ 's exists. Thus there are zerosets $Z_{0}, Z_{1}, \ldots, Z_{n}$ in $\Gamma_{2}^{\prime} C(X)$ such that $p_{i} \in Z_{i}$, for every $0 \leq i \leq n$, and $i \neq j$ implies $Z_{i} \cap Z_{j}=\emptyset$. Set $Z(g)=Z_{1} \cup Z_{2} \cup \cdots \cup Z_{n}$. Then $p_{0} \notin Z(g) \neq X$ and $p_{i} \in Z(g) \cap Z\left(f_{i}\right) \neq \emptyset$, thus $g \in \Gamma_{2}^{\prime} C(X)$ and not adjacent to any $f_{i}$. This follows that $A$ is not a dominating set.
Theorem 4.4. $d(X) \leq \mathrm{dt} \Gamma_{2}^{\prime} C(X) \leq w(X)$. In particular, whenever $d(X)=$ $w(X)$, then $\mathrm{dt} \Gamma_{2}^{\prime} C(X)=w(X)$.
Proof: If $X$ is finite, then it is easy to check $d(X)=\mathrm{dt} \Gamma_{2}^{\prime} C(X)=w(X)$, thus we assume $X$ is infinite. Let $A$ be a dominating set in $\Gamma_{2}^{\prime} C(X)$. For each $f \in A$, we pick $x_{f} \in Z(f)$ and $y_{f} \in \operatorname{Coz}(f)$. Set $D=\left\{x_{f}: f \in A\right\} \cup\left\{y_{f}: f \in A\right\}$. For every cozeroset $\operatorname{Coz}(g)$, if $g \in A$, then $y_{g} \in D \cap \operatorname{Coz}(g)$, if $g \notin A$, then $f \in A$ exists such that

$$
Z(f) \cap Z(g)=\emptyset \quad \Rightarrow \quad Z(f) \subseteq \operatorname{Coz}(g) \quad \Rightarrow \quad x_{f} \in Z(f) \cap D \subseteq \operatorname{Coz}(g) \cap D
$$

Hence $D$ is dense in $X$. Since $D$ is infinite, $d(X) \leq \mathrm{dt} \Gamma_{2}^{\prime} C(X)$.
We now suppose that $\mathcal{B}$ is a base for $X$. Without loss of generality we can assume that $\mathcal{B}$ does not have any empty members. Then for every $B \in \mathcal{B}$, there
is some $f_{B}$ in $\Gamma_{2}^{\prime} C(X)$ such that $Z\left(f_{B}\right) \subseteq B$. For each $f$ in $\Gamma_{2}^{\prime} C(X)$ there is some $B$ in $\mathcal{B}$ such that

$$
Z\left(f_{B}\right) \subseteq B \subseteq \operatorname{Coz}(f) \quad \Rightarrow \quad Z\left(f_{B}\right) \cap Z(f)=\emptyset
$$

By Lemma 1.2, $f$ is adjacent to $f_{B}$. Therefore $\left\{f_{B}: B \in \mathcal{B}\right\}$ is a dominating set and finally that $\mathrm{dt} \Gamma_{2}^{\prime} C(X) \leq w(X)$.

An immediate conclusion of the above theorem is the following corollary.
Corollary 4.5. If $X$ is an infinite second countable space, then $\mathrm{dt}^{\prime} \Gamma_{2}^{\prime} C(X)=\omega$.
Example 4.6. Let $X$ be Moore plane. For every ( $x_{\circ}, y_{\circ}$ ) in $X$, set $f_{x_{\circ}, y_{\circ}}$ : $X \rightarrow \mathbb{R}$ as $f_{x_{\circ}, y_{\circ}}(x, y)=\sqrt{\left(x-x_{\circ}\right)^{2}+\left(y-y_{\circ}\right)^{2}}$. It is clear that $f \in \Gamma_{2}^{\prime} C(X)$ and $Z\left(f_{x_{\circ}, y_{\circ}}\right)=\left\{\left(x_{\circ}, y_{\circ}\right)\right\}$. Suppose $A=\left\{f_{x, y}: x, y \in \mathbb{Q}\right.$ and $\left.y>0\right\}$. If $Z(f) \cap Z\left(f_{x, y}\right) \neq \emptyset$, for each $f_{x, y} \in A$, then $\mathbb{Q} \times \mathbb{Q}^{>0} \subseteq Z(f)$ and therefore $X Z(f)$. This implies that $A$ is a dominating set and therefore $\mathrm{dt} \Gamma_{2}^{\prime} C(X)=\omega \neq \mathbf{c}=\omega(X)$.
Proposition 4.7. Suppose $\Gamma C(X)$ is the zero divisor graph of $C(X)$. If $\chi(X) \leq$ $d(X)$, then $\mathrm{dt} \Gamma_{2}^{\prime} C(X)=d(X)=\mathrm{dt} \Gamma C(X)$.
Proof: According to Theorem 4.4, we only need to show that $d(X) \geq \mathrm{dt} \Gamma_{2}^{\prime} C(X)$. Clearly, if $X$ is finite, then $\mathrm{dt} \Gamma_{2}^{\prime} C(X)=d(X)$.

Now suppose $X$ is infinite, then every dominating set is infinite, by Lemma 4.3. Let $D$ be a dense subset of $X$ and $\mathfrak{B}_{x}$ is a neighborhood base at $x$, for each $x$ in $D$. For every $x \in D$ and $B \in \mathfrak{B}_{x}$, there is some $f_{x, B} \in \Gamma_{2}^{\prime} C(X)$ such that $x \in Z\left(f_{x, B}\right) \subseteq B$. Put $A=\left\{f_{x, B}: x \in D\right.$ and $\left.B \in \mathfrak{B}_{x}\right\}$. If $g \in \Gamma_{2}^{\prime} C(X)$, then $\operatorname{Coz}(g) \neq \emptyset$, and it follows that $x \in D \cap \operatorname{Coz}(g)$ exits. Hence there is a $B \in \mathfrak{B}_{x}$ such that $Z\left(f_{B, x}\right) \subseteq B \subseteq \operatorname{Coz}(g)$, thus $Z\left(f_{B, x}\right) \cap Z(g)=\emptyset$, and, in consequence, $f_{B, x}$ is adjacent to $g$. This implies that $A$ is dominating set. Since $|A| \leq \chi(X)|D| \leq d(X) d(X)=d(X), d(X) \geq \mathrm{dt} \Gamma_{2}^{\prime} C(X)$. The equality $\mathrm{dt} \Gamma C(X)=d(X)$ was shown in [12, Proposition 3.4].

By [17, Thorem 1.5.7], $w(X) \leq \exp d(X)$, hence the following corollary is immediate.

Corollary 4.8. $d(X) \leq \mathrm{dt} \Gamma_{2}^{\prime} C(X) \leq \exp d(X)$.
Definition 4.9. We define zero cellularity of $X$, denoted by $z c(X)$, by the supremum of $\{|\mathcal{Z}|: \mathcal{Z}$ is a family of pairwise disjoint nonempty zero subsets of $X\}$.
Theorem 4.10. We have clique $\Gamma_{2}^{\prime} C(X)=z c(X) \leq|X|$. In particular if $X$ is first countable, then clique $\Gamma_{2}^{\prime} C(X)=z c(X)=|X|$.
Proof: By Lemma $1.2, A \subseteq \Gamma_{2}^{\prime} C(X)$ is a complete subgraph of $\Gamma_{2}^{\prime} C(X)$ if and only if $Z(A)=\{Z(f): f \in A\}$ is a family of pairwise disjoint zerosets, thus clique number of $\Gamma_{2}^{\prime} C(X)$ is the supremum of

$$
\{|\mathcal{Z}|: \mathcal{Z} \text { is a family of pairwise disjoint zero sets of } X\}
$$

hence clique $\Gamma_{2}^{\prime} C(X)=z c(X)$. It is clear that $z c(X) \leq|X|$.

If $X$ is first countable, then for every $p$ in $X,\{p\}$ is a zeroset and thus $z c(X)=$ $|X|$.

## 5. Some applications

Theorem 5.1. $\Gamma_{2}^{\prime} C(X)$ is triangulated if and only if $X$ does not have any isolated points.

Proof: $\Rightarrow$ If $p$ is an isolated point of $X$, then there is some $f$ in $\Gamma_{2}^{\prime} C(X)$ such that $\operatorname{Coz}(f)=\{p\}$, thus $f$ is not a vertex of a triangle, by Lemma 3.1. Consequently, $\Gamma_{2}^{\prime} C(X)$ is not triangulated.
$\Leftarrow$ Suppose $\Gamma_{2}^{\prime} C(X)$ is not triangulated, hence there is some $f$ in $\Gamma_{2}^{\prime} C(X)$ such that $f$ is not a vertex of any triangle. By Lemma 3.1, $\operatorname{Coz}(f)=\{p\}$ is singleton, hence $p$ is an isolated point of $X$.

Theorem 5.2. $\Gamma_{2}^{\prime} C(X)$ is hypertriangulated if and only if $X$ is connected.
Proof: $\Rightarrow$ If $X$ is disconnected, then there are zerosets $Z(f)$ and $Z(g)$ such that $Z(f) \cap Z(g)=\emptyset$ and $Z(f) \cup Z(g)=X$. From Lemma 4.1, gi $(f, g)=4$, which yields $\{f, g\}$ is not edge of any triangle, and therefore $\Gamma_{2}^{\prime} C(X)$ is not hypertriangulated.
$\Leftarrow$ Suppose $\Gamma_{2}^{\prime} C(X)$ is not hypertriangulated. Then there is an edge $\{f, g\}$ of $\Gamma_{2}^{\prime} C(X)$, which is not an edge of any triangle, thus gi $(f, g)=4$. Lemma 4.1 now shows that $Z(f) \cup Z(g)=X$ and $Z(f) \cap Z(g)=\emptyset$, this implies $X$ is disconnected.

Theorem 5.3. $\Gamma_{2}^{\prime} C(X)$ is complemented if and only if $X$ is a $P$-space.
Proof: $\Rightarrow$ For every zeroset $Z(f)$ there is a zeroset $Z(g)$ such that $f \perp g$, thus $\operatorname{gi}(f, g)=3$. We conclude from Lemma 4.1 that $\operatorname{Coz}(f) \cap \operatorname{Coz}(g)=\emptyset$ and $\operatorname{Coz}(f) \cup \operatorname{Coz}(g)=X$, therefore $Z(f)$ is open. This follows that $X$ is a $P$-space.
$\Leftarrow$ For every vertex $f$ in $\Gamma_{2}^{\prime} C(X), Z(f)$ is open, thus $g$ in $\Gamma_{2}^{\prime} C(X)$ exists such that $Z(f) \cap Z(g)=\emptyset$ and $Z(f) \cup Z(g)=X$. Now Lemma 4.1 becomes gi $(f, g)=3$, thus $f \perp g$ and consequently $\Gamma_{2}^{\prime} C(X)$ is complemented.

Lemma 5.4. Suppose $M^{p}$ is a maximal ideal of $C(X)$, for some $p \in \beta X$. Then $M^{p}$ is principal if and only if $p$ is an isolated point.

Proof: $\Rightarrow$ Let $M^{p}=\langle f\rangle$, for some $f \in C(X) . Z(f)=\{p\}$, since $\bigcap_{Z \in Z\left(M^{p}\right)} Z=$ $Z(f)$. If $p$ is not an isolated point, then $p \in \overline{\operatorname{Coz}(f)}$, and therefore there is a net $\left(x_{\lambda}\right)$ in $\operatorname{Coz}(f)$, which converges to $p$. We conclude from $Z\left(f^{\frac{1}{3}}\right)=Z(f)$ that there is some $g$ in $C(X)$ such that $f^{\frac{1}{3}}=g f$, hence that $g(x)=1 / f^{\frac{2}{3}}(x)$, for each $x$ in $\operatorname{Coz}(f)$, therefore $g(p)=\lim g\left(x_{\lambda}\right)=\infty$, which is a contradiction.
$\Leftarrow$ It is straightforward.
Proposition 5.5. Let $p$ be a $G_{\delta}$-point of $X$. If $Z(f)=\{p\}$, then

$$
M^{p}=\left\{g \in \Gamma_{2}^{\prime} C(X): d(f, g)=2\right\} \cup\{0, f\}
$$

Proof: Set $I=\left\{g \in \Gamma_{2}^{\prime} C(X): d(f, g)=2\right\} \cup\{0, f\}$. If $g \in M^{p}$, then $p \in Z(g)$, hence $Z(f) \cup Z(g) \neq X$ and $Z(f) \cap Z(g) \neq \emptyset$. Lemma 2.1 shows that $d(f, g)=2$, and therefore $M^{p} \subseteq I \quad$ (1).

Now suppose $g \in I$. Since $d(f, g)=2,\{p\} \cap Z(g)=Z(f) \cap Z(g) \neq \emptyset$. This implies $p \in Z(g)$, and thus $g \in M^{p}$. Hence $I \subseteq M^{p}$ (2). By (1) and (2), $M^{p}=I$.

Theorem 5.6. The following are equivalent.
(a) $X$ is an almost $P$-space which does not have any isolated points.
(b) $C(X)$ is almost regular ring which does not have any principal maximal ideals.
(c) $\operatorname{Rad} \Gamma_{2}^{\prime} C(X)=3$.
(d) For each $f \in \Gamma_{2}^{\prime} C(X)$, there is some $g \in \Gamma_{2}^{\prime} C(X)$ such that $\operatorname{gi}(f, g)=6$.

Proof: (a) $\Leftrightarrow$ (b) By Lemma 5.4 it is obvious.
(a) $\Rightarrow$ (c) For each $f \in \Gamma_{2}^{\prime} C(X), \operatorname{int} Z(f) \neq \emptyset$, thus $\operatorname{ecc}(f)=3$. Hence $\operatorname{Rad} \Gamma_{2}^{\prime} C(X)=3$.
$(c) \Rightarrow$ (a) Since $\operatorname{Rad} \Gamma_{2}^{\prime} C(X)=3$, for every $f \in \Gamma_{2}^{\prime} C(X)$ we have $\operatorname{ecc}(f)=3$. We conclude from Proposition 2.3, that $\operatorname{int} Z(f) \neq \emptyset$ and $X$ does not have any isolated points, hence that $X$ is an almost $P$-space without any isolated points.
$(\mathrm{d}) \Rightarrow(\mathrm{b})$ For each $f \in \Gamma_{2}^{\prime} C(X)$, there is some $g \in \Gamma_{2}^{\prime} C(X)$ such that gi $(f, g)=$ 6, thus $Z(f) \cap Z(g) \neq \emptyset$ and $Z(f) \cup Z(g)=X$. We conclude that $f$ is a zero divisor and consequently $C(X)$ is an almost regular ring.
(c) $\Rightarrow(\mathrm{d})$ Since $\operatorname{Rad} \Gamma_{2}^{\prime} C(X)=3$, for each $f \in \Gamma_{2}^{\prime} C(X)$ we have $\operatorname{ecc}(f)=3$, thus $g$ in $\Gamma_{2}^{\prime} C(X)$ exists such that $d(f, g)=3$ and therefore $\operatorname{gi}(f, g)=6$.

Proposition 5.7. The following statements are equivalent.
(a) $C(X)$ is almost regular ring which has some principal maximal ideal.
(b) $X$ is an almost $P$-space which has some isolated point.
(c) $\operatorname{Rad} \Gamma_{2}^{\prime} C(X)=2$ and for each $f$ in the center of $\Gamma_{2}^{\prime} C(X)$ there is $g \in$ $\Gamma_{2}^{\prime} C(X)$ such that $\{f, g\}$ is an edge of a square.

Proof: (a) $\Leftrightarrow$ (b) By Lemma 5.4, it is evident.
(b) $\Rightarrow$ (c) By Theorem 5.6, $\operatorname{Rad} \Gamma_{2}^{\prime} C(X)=2$, thus for every $f$ in center of $\Gamma_{2}^{\prime} C(X), \operatorname{ecc}(f)=2$. Theorem 5.4 shows that $Z(f)=\{p\}$, for some isolated point $p$. Hence $g \in \Gamma_{2}^{\prime} C(X)$ exists such that $\operatorname{Coz}(g)=\{p\}$. Since $Z(f) \cap Z(g)=\emptyset$ and $Z(f) \cup Z(g)=X$, by Lemma 4.1, $\{f, g\}$ is an edge of a square.
(c) $\Rightarrow$ (b) If $Z(f)=\emptyset$, for some $f \in \Gamma_{2}^{\prime} C(X)$, then $f$ belongs to the center of $\Gamma_{2}^{\prime} C(X)$. This implies that there is a $g \in \Gamma_{2}^{\prime} C(X)$ such that $\{f, g\}$ is an edge of some square, thus $Z(f)$ is open, by Lemma 4.1, a contradiction. Since $\operatorname{Rad} \Gamma_{2}^{\prime} C(X)=2$, from Theorem 5.6, $X$ has some isolated point.

Acknowledgments. We are very grateful to the referee whose valuable suggestions and comments improved an earlier version of this article.
