I. result of $J$. Bourgain: $C\left(L^{1}\right)$ has the Dunford-Pettis property

by Walter Schachermayer

This note which proves the anounced theorem is entirely based on [i]. We hope that we have succeeded to make the proof more accessible from the pedagogical point of view, but we want to stress out that there is no iciea used here tha has not been used in [1]. Also more general results are obtained in [1].

Let $(S, \Sigma, \mu)$ be a probability space and $T$ be the Cantor set (this is only for convenience; the result carries over to arbitrary compact Hausdorff spaces by some obvious modifications of the proof). Denote by $C\left(T ; L^{1}(\mu)\right)$ or short $C\left(L^{1}\right)$ the space of continuous functions from $T$ to $L^{1}(\mu)$.

Theorem: $C\left(L^{1}\right)$ has the Dunford-Pettis property.

Proof: If $C\left(L^{1}\right)$ does not have $D-P$, then there exist a sequence $\left\{\xi^{i}\right\}_{i=1}^{\infty}$ in $C\left(L^{1}\right)$ and a soquence $\left\{\mu^{j}\right\}_{i=1}^{\infty}$ in $C\left(L^{1}\right)^{*}$, botin tending weakly to zero, and $a>0$ such that. $\left\langle\xi^{i}, \mu^{i}\right\rangle \leq \propto$ (c.f. [3]). Clearly we may assume that $\left\|\xi^{i}\right\|,\left\|\mu^{i}\right\| \leqq 1$ and that $\xi^{i}$ are finitely valued functions (as the Cantor set is totally discorinectea). So let us work

Clearly for each $t \in T$, the sequence $\left\{\xi_{t}^{i}\right\}_{i=1}^{\infty}$ is a weak nullsequence in $L^{1}(\mu)$. Indeed, for $t \in T$ and $g \in L^{\infty}(\mu)$ the function $\xi \rightarrow\left\langle\xi_{t}, g\right\rangle$ is an element of $\left(C_{L} 1\right)^{*}$.

Now we give the following intuitive hint: a. sequence in $L^{1}(\mu)$ may only converge in two ways weakly to zero: it either converges strongly (this case is trivial for our purposes), or - if it does not converge strongly - it behaves "essentially like the Rademacherfunctions". This hint is made precise in the following technical arguments (which are standard), where we show that we may reduce to the case stated below ((A)). At a fist reading the reader is advised to skip the following reduction steps and to continue at (A), as it is only then, that the essence of Bourgain's argument (namely the use of Riesz-products) comes up.

Let $\left|\mu^{i}\right|$ denote the variation measure of $\mu^{i}$, i.e. $\left|\mu^{i}\right|$ is the linear functional on $C(T)$ defined for $x \in C(T)_{+}$by

$$
\langle x,| \mu^{i}| \rangle=\sup \left\{\left\langle\xi, \mu^{i}\right\rangle:\left\|\xi_{t}\right\| \leqq x(t) \quad \forall t \in T\right\}
$$

Let $\nu={ }_{i} \stackrel{D}{=}_{1} 2^{-i}\left|\mu^{i}\right|$; clearly the sequence $\left\{\left|\mu^{i}\right|\right\}_{i=1}^{\infty}$ is equi-absolutely continuous with respect to $v$. Indeed, if this were not so, we could find by Rosenthal.'s lemma (c.f. [2], N.2.) a disjoint sequence $\left\{A_{k}\right\}_{k=1}^{\infty}$ of Bored subsets of. $T$, an increasing sequence $\left\{i_{k}\right\}_{k=1}^{\infty}$ and $\varepsilon>0$ such that $\left|\mu^{i_{k}}\right|\left(A_{k}\right) \geqq \varepsilon$ and $\left|\mu{ }^{i_{k}}\right|\left(\underset{\substack{j=1 \\ \bigcup_{j} \\ j \neq k}}{\infty} A_{j}\right)<\varepsilon / 2$. This would imply that $\left|\mu^{i_{k}}\right|$ spans an $\ell^{1}$ in $M(K)$ and similarly that $\mu^{i_{k}}$ spans,a $\ell^{1}$ in $\left(C_{L}\right)^{*}$, which contradicts the weal convergence - Of $\mu^{i}$.

So there is $\delta>0$ such that for a Borel-set $A \subseteq T$, $\nu(A) \leq 0$ implies $\left|\mu^{i}\right|(A) \leq \alpha / 3$ for every $i \in \mathbf{N}$.

As has already been observed, for $t \in T$, the sequence $\left\{\xi_{t}^{i}\right\}_{i=1}^{\infty}$ converges weakly in $L^{1}(\mu)$, hence there exists a constant $M_{t}$ such that for every $i \in \mathbb{N}$
 $t \rightarrow M_{t}$ to be $v$-measurable so we may find a constant $M$ such that for every $t$ in some compact subset $T_{0}$ of $T$, with $v\left(T \backslash T_{0}\right)<\delta$, we have $\left\|\xi_{t}^{i} \cdot X_{\left\{\left|\xi_{t}^{i}\right|>M\right\}}\right\|<\alpha / 9$.

We now start an induction: We shall construct a decreasing sequence $T_{k}$ of compact subsets of $T$, with $v\left(T \backslash T_{k}\right)<\delta$, an increasing sequence $\left\{i_{k}\right\}_{k=1}^{\infty}$ of integers and for every $t \in T_{k}$ we shall define an element $\psi_{t}^{k}$ of $L^{1}(\mu)$ and a finite sub-o-algebra $B_{t}^{k}$ of $\Sigma$, containing $B_{t}^{k-1}$, such that

$$
\begin{equation*}
\left\|\psi_{t}^{k}\right\|_{L}^{\infty}(\mu) \leqq 2 M \tag{i}
\end{equation*}
$$

$$
\begin{equation*}
\left\|\psi_{t}^{k}-\xi_{t}^{i_{k}}\right\|_{L}{ }^{1}(\mu)<\alpha / 3 \tag{ii}
\end{equation*}
$$

$\psi_{t}^{k}$ is $B_{t}^{k}$ - measurable and $E\left(\psi_{t}^{k} \mid B_{t}^{k-1}\right)=0$. Let $B{ }_{t}^{O}=\{\phi, S\}$.
For $k=1$ note that for $t \in T_{0}, E\left(\xi_{t}^{k}\right)$ tends to zero; hence we may find $T_{1} \subseteq T_{0}, \mu\left(T \backslash T_{1}\right)<\delta$ and an integer $i_{1}$ such that for $t \in T_{1}\left|E\left(\xi_{t}^{i_{1}}\right)\right|<\alpha / 9$. We may find a simple function $\varphi_{t}^{1},\left\|\varphi_{t}^{1}\right\|_{L}^{\infty}(\mu) \leqq M$, such that $\left\|\varphi_{t}^{1}-\xi_{t}^{i}\right\|_{L}^{1}(\mu)<\alpha / 9$. Note that this implies that $\left|E\left(\varphi_{t}^{1}\right)\right| \leqq\left|E\left(\xi_{t}^{1}\right)\right|+\left|E\left(\varphi_{t}^{1}-\xi_{t}^{1}\right)\right|<\frac{2}{9}$

Let $\psi_{t}^{1}=\varphi_{t}^{1}-E\left(\varphi_{t}^{1}\right)$ and $B_{t}^{1}$ a finite sub-o-algebra of г. such that $\psi_{t}^{1}$ is $B_{t}^{1}$ measurable, and check that (i), (ii) and (iii) are satisfied.

For the induction step suppose $T_{k}, i_{k}$ and $\Psi_{t}^{k}$ and $B_{t}^{k}$ for $t \in T_{k}$ defined. Fix $t \in T_{k}$. As $B_{t}^{k}$ is a finite $\sigma$-algebra $E\left(\xi_{t}^{i} \mid B_{t}^{k}\right.$ ) tends to zero (in the $L^{1}$-norm, say). So we may find $\mathrm{T}_{\mathrm{k}+1} \subseteq \mathrm{~T}_{\mathrm{k}}, \mu\left(\mathrm{T} \backslash \mathrm{T}_{\mathrm{k}+1}\right)<\delta$, and an integer $i_{k+1}>i_{k}$ such that, for $t \in T_{k+1},\left\|E\left(\xi_{t}^{i_{k+1}} \mid B_{t}^{k}\right)\right\|_{L}{ }^{1}(\mu)<\alpha / 9$. Again we may find a simple function $\varphi_{t}^{k+1},\left\|\varphi_{t}^{k+1}\right\|_{L}^{\infty}(\mu) \leq M$, such that $\left\|\varphi_{t}^{k+1}-\xi_{t}^{i_{k+1}}\right\|_{L}{ }^{1}(\mu)<\alpha / 9$. As above this implies $\left\|E\left(\varphi_{t}^{k+1} \mid B_{t}^{k}\right)\right\|_{L}^{1}(\mu)<\frac{2 \alpha}{9}$. Putting $\psi_{t}^{k+1}=\varphi_{t}^{k+1}-E\left(\varphi_{t}^{k+1} \mid B_{t}^{k}\right)$ and $B_{t}^{k+1}$ a finite $\sigma$-algebra, containing $B_{t}^{k}$, such that $\psi_{t}^{k+1}$ is $B_{t}^{k+1}$-measurable, it is immediate to check that these satisfy (i), (ii) and (iii).

Finally let us observe the following: We have assumed the $\xi_{t}^{i}$ to be simple functions and we may clearly assume that for $t_{1}, t_{2} \in T_{k}$ such that $\xi_{t_{1}}^{i_{k}}=\xi_{t_{2}}^{i_{k}}$ we have applied the same construction to it, i.e. $\varphi_{t_{1}}^{k}=\varphi_{t_{2}}^{k}$. This implies that the functions $t \rightarrow \varphi_{t}^{k}$ are (simple) continuous functions on $T_{k}$, a fact which is not really essential for the following arguments, but has some cosmetic convenience for our formulation of the assumption (A).

Let $\bar{T}=\bigcap_{k}^{\infty} \mathrm{N}_{1} T_{k}$ and note that $\nu(T \backslash \bar{T}) \leqq \delta$.
Let $\overline{\boldsymbol{F}}_{t}^{k} \in \mathrm{C}\left(\overline{\mathrm{T}} ; \mathrm{L}^{1}(\mu)\right)$ be defined by $\overline{\boldsymbol{\xi}}_{t}^{k}=(2 M)^{-1}{ }_{\mathrm{\psi}}^{\mathrm{k}}$ for $t \in \bar{T}$ and let $\bar{\mu}^{-k} \in C\left(\bar{T} ; L^{1}(\mu)\right)^{*}$ the restriction of $\mu^{i k}$ to $\bar{T}$.

Then

$$
\begin{aligned}
&\left\langle 2 M \bar{\xi}^{k}, \bar{\mu}^{k}\right\rangle \geq\left\langle\xi^{i_{k}}, \mu^{i_{k}}\right\rangle-\left|\left\langle\xi_{t}^{i_{k}, \mu}{ }^{i_{k}} \cdot x_{T \backslash T}\right\rangle\right| \\
&-\left|\left\langle\dot{\xi}_{t}^{i_{k}}-\psi_{t}^{k} \cdot \mu^{i_{k}} x_{\bar{T}}\right\rangle\right| \\
& \geq \alpha-\alpha / 3-\alpha / 3=\alpha / 3,
\end{aligned}
$$

i.e. $\quad\left\langle\bar{\xi}^{k}, \bar{\mu} k\right\rangle \geq \frac{\alpha}{6 M}=\bar{\alpha}$.

Writing $\xi^{i}$ instead of $\bar{\xi}^{k}$ and $\mu^{i}$ instead of $\bar{\mu}^{k}$ for $i=k$ and $\alpha$ instead of $\bar{\alpha}$, we arrive at our desired assumtic
(A) If $C\left(T ; L^{1}\right)$ does not have the Dunford-Pettis property, then there is a compact subspace $\bar{T}$ of $T$, and sequences $\left\{\xi^{i}\right\}_{i=1}^{\infty} \in C\left(\bar{T}, L^{1}\right)$ and $\left\{\mu^{i}\right\}_{i=1}^{\infty} \in C\left(\bar{T} ; L^{1}\right)^{*},\left\|\xi^{i}\right\|\left\|\mu^{i}\right\| \leqq 1$, both tending weakly to zero and an $\alpha>0$ such that $\left\langle\xi^{i}, \mu^{i}\right\rangle \geq \alpha$ and
(1) For each $t \in \bar{T}$ and $i \in \mathbb{N} \boldsymbol{\xi}_{t}^{i}$ belongs to $L^{\infty}(\mu)$ and $\left\|\boldsymbol{\xi}_{t}^{i}\right\|_{L^{\infty}(\mu)} \leq 1$
(2) For each $t \in \bar{T}$ the sequence $\left\{\xi_{t}^{i}\right\}_{i=1}^{\infty}$ is a martingale difference sequence, ie. there exists an increasing sequence of (finite) $\sigma$-algebras $\left\{B_{t}^{i}\right\}_{i=0}^{\infty}$ on $S$, $B_{t}^{0}=\{\phi, S\}$, such that $\xi_{t}^{i}$ is $B_{t}^{i}$-measurable and $E\left(\xi_{t}^{i} \mid B_{t}^{i-1}\right)=0 \quad$ for $\quad i \in N$.
Note that (2) implies clearly
(2') for each $t \in \bar{T}$ and $i_{1}<i_{2}<\ldots<i_{k}$

$$
E\left(\xi_{t}^{i_{1}} \cdot \xi_{t}^{i_{2}} \cdot \cdots \cdot \xi_{t}^{i_{k}^{e}}\right)=0
$$

and it is this latter property of $\left\{\xi_{t}^{i}\right\}_{i=1}^{\infty}$, which will be used in the sequel.

By the subsequent lemma we may find positive scalars
$a_{1}, \ldots, a_{n}, \sum_{i=1}^{n} a_{i}=1$ such that $\left\|_{i} \stackrel{N}{\underline{E}}_{1} a_{i} \varepsilon_{i} \mu^{i}\right\|<\alpha / 2$ for every choice of sighs $\varepsilon_{i}= \pm 1$. Denoting by $\varepsilon_{i}$ the $i-t h$ Rademacher-function on $[0,1]$, this is the same as saying $\left\|_{i}{\underset{=}{=}}_{1} a_{i} \varepsilon_{i}(\omega) \mu^{i}\right\|<\alpha / 2$ for every $\omega \in[0,1]$.

Now define for $\omega \in[0,1]$ the (Riesz)-products $R_{\omega} \in C_{L}{ }^{1}$ by letting for $t \in \bar{T}$

$$
R_{\omega, t}=\prod_{i=1}^{n}\left(1+\varepsilon_{i}(\omega) \xi_{t}^{i}\right)
$$

Clearly for each $\omega \in[0,1]$ and $t \in \bar{T}, R_{\omega, t} \geq 0$ and $\left\|R_{\omega, t}\right\|_{L} 1=E\left(\prod_{i=1}^{n}\left(1+\varepsilon_{i}(\omega) \xi_{t}^{i}\right)\right)=1$ as (b ye')) for every $i_{1}<i_{2}<\cdots \leqslant i_{k}, E\left(\xi_{t}^{i_{1}} \cdot \cdots \xi_{t}^{i_{k}}\right)=0$.
Also note that for $1 \leq j \leqq n$ and $t \in T$
${\underset{[0,1]}{\delta} \varepsilon_{j}(\omega)}^{R_{\omega, t}} d \omega=\underset{[0,1]}{\int} \varepsilon_{j}(\omega) \cdot \prod_{i=1}^{n}\left(1+\varepsilon_{i}(\omega) \xi_{t}^{i}\right) d \omega=\xi_{t}^{j}$.

Recapitulating, what we have done so far: Starting from $\mu^{1}, \ldots, \mu^{n}$ we have formed the $2^{n}$ convex combinations $\sum_{i=1}^{n} a_{i} \varepsilon_{i} \mu^{n} \quad\left(\varepsilon_{i}= \pm 1\right)$. On the other hand we have formed, starting form $\xi^{1}, \ldots, \xi^{n}$, the Rieszproduct $R_{\omega}$ (which are also in reality $2^{n}$ elements).

We may obtain the, $\mu^{i}$ back from the ${ }_{i} \sum_{1}^{n} a_{i} \varepsilon_{i} \mu^{i}$ as their "Rademacher-averages" just in the same way as we may get the $\xi^{i}$ back from the $R_{\omega}$. This and the fact that we could make the norms of the $\sum_{i=1}^{\underline{E}} a_{i} \varepsilon_{i} \mu^{i}$ small while the norms of the $R_{\omega}$ 's stay bounded, leads to the following contradiction
which finishes the proof of the theorem:

$$
\begin{aligned}
& \frac{a}{2}>\int_{[0,1]}\left\|R_{\omega}\right\| \cdot\left\|_{i} \sum_{1}^{n} a_{i} \varepsilon_{i}(\omega) \mu^{i}\right\| d \omega \\
& 2 \underset{[0,1]}{\int}\left\langle R_{\omega^{\prime}} i_{i=1}^{n} \dot{\underline{E}}_{i} \varepsilon_{i}(\omega) \mu^{i}\right\rangle d \omega \\
& =\sum_{i=1}^{n} a_{i}\left\langle\underset{[0,1]}{\rho} \varepsilon_{i}(\omega) R_{\omega} d \omega, \mu^{i}\right\rangle \\
& =i_{i=1}^{\dot{n}} a_{i}\left\langle\xi^{i}, \mu^{i}\right\rangle \geq \alpha .
\end{aligned}
$$

q.e.d.

We still have to prove a lemma, which is folklore (as is its proof also).

Lemma: Let $\left\{\eta^{i}\right\}_{i=1}^{\infty}$ be a weak null sequence in a Banach space $Y$. For $\varepsilon>0$ there is a finite sequence $a_{1}, \ldots, a_{n}$ of positive scalars, $\sum_{i=1}^{n} a_{i}=1$, such that for all choices of signs $\varepsilon_{i}= \pm 1$ the norm $\left\|_{i} \sum_{1}^{n} \varepsilon_{i} a_{i} \eta^{i}\right\|$ is less than $\varepsilon$.

Proof: By the Banach - Mazur and the Hahn - Banach theorem there is no loss in assuming $Y=C_{[0,1]}$, i.e. the $\eta^{1}$ are continuous functions on $[0,1]$. It follows easily from Grothendieck's characterisation of weak convergence in $C_{[0,1]}$ ( pointwise convergence + uniform boundedness) that $\eta^{i}$ converges weakly to zero iff $\left|\eta^{i}\right|$ does so. It is wellknown that we may choose a convex combination $\sum_{i} \underline{E}_{1} a_{i}\left|\eta^{i}\right|$ of norm less than $\varepsilon$. But this clearly implies that for each $\varepsilon_{i}= \pm 1$

$$
\left\|_{1} \sum_{\underline{\underline{n}}} \varepsilon_{i} a_{i} \eta^{i}\right\|<\varepsilon
$$

I want to note, that we may proof by the same techniques that $L^{1}(\mu ; C(T))$ has the Dunford-Pettis property. But at this stage, the reader is advised to consult Bourgain's original paper, where using local results about Banach spaces, more general results are obtained. Here I only wanted to make the essence of Bourgain's proof more accesible.

Finally let us note that the problem, if the DunfordPettis property for a Banach space X implies the same property for $C(T ; X)$ or $L^{1}(\mu ; X)$ remains open.
