# LIMITED-MEMORY VARIABLE METRIC METHODS THAT USE QUANTITIES FROM THE PRECEDING ITERATION* 

Jan Vlček, Ladislav Lukšan

## 1. Introduction

In this contribution, a new family of globally convergent limited-memory (LM) variable metric (VM) line search methods for unconstrained minimization is presented. Numerical results indicate that the new methods can save computational time substantially for certain problems in comparison with the well-known L-BFGS method, see [3], [8].

VM or quasi-Newton line search methods, see [2], [4], start with an initial point $x_{0} \in \mathcal{R}^{N}$ and generate iterations $x_{k+1} \in \mathcal{R}^{N}$ by the process $x_{k+1}=x_{k}+s_{k}, s_{k}=t_{k} d_{k}$, $k \geq 0$, where $d_{k}$ is the direction vector and $t_{k}>0$ is a stepsize.

It is assumed that the problem function $f: \mathcal{R}^{N} \rightarrow \mathcal{R}$ is differentiable and stepsize $t_{k}$ is chosen in such a way that

$$
\begin{equation*}
f_{k+1}-f_{k} \leq \varepsilon_{1} t_{k} g_{k}^{T} d_{k}, \quad g_{k+1}^{T} d_{k} \geq \varepsilon_{2} g_{k}^{T} d_{k} \tag{1}
\end{equation*}
$$

$k \geq 0$, where $0<\varepsilon_{1}<1 / 2, \varepsilon_{1}<\varepsilon_{2}<1, f_{k}=f\left(x_{k}\right), g_{k}=\nabla f\left(x_{k}\right)$ and $d_{k}=-H_{k} g_{k}$ with a symmetric positive definite matrix $H_{k}$; usually $H_{0}$ is a multiple of $I$ and $H_{k+1}$ is obtained from $H_{k}$ by a rank-two VM update to satisfy the quasi-Newton condition $H_{k+1} y_{k}=s_{k}$ (see [2], [4]), where $y_{k}=g_{k+1}-g_{k}, k \geq 0$. For $i \geq 0$ we denote

$$
b_{i}=s_{i}^{T} y_{i}, \quad V_{i}=I-\left(1 / b_{i}\right) s_{i} y_{i}^{T}
$$

(note that $s_{i}^{T} y_{i}>0$ for $g_{i} \neq 0$ by (1)). To simplify the notation we frequently omit index $k$ and replace index $k+1$ by symbol + and index $k-1$ by symbol - .

The L-BFGS method (LM variant of the well-known BFGS method, see [3], [8]) is based on the following quasi-product form of the BFGS update

$$
\begin{equation*}
H_{+}=(1 / b) s s^{T}+V H V^{T} . \tag{2}
\end{equation*}
$$

The advantage of this form consists in the fact that only the last $\tilde{m}+1=\min (k+1, m)$ couples $\left\{s_{i}, y_{i}\right\}_{i=k-\tilde{m}}^{k}$, where $m \geq 1$ is a given parameter, are stored to compute the direction vector $d_{k+1}=-H_{k+1} g_{k+1}$ by the Strang recurrences, see [8]. Matrices $H_{k+1}$ are not computed, only defined by $H_{k+1}=H_{\tilde{m}+1}^{k+1}, k \geq 0$, where

$$
\begin{align*}
H_{0}^{k+1} & =\left(b_{k} /\left|y_{k}\right|^{2}\right) I  \tag{3}\\
H_{i+1}^{k+1} & =\left(1 / b_{j}\right) s_{j} s_{j}^{T}+V_{j} H_{i}^{k+1} V_{j}^{T}, \quad j=k-\tilde{m}+i, \quad 0 \leq i \leq \tilde{m} . \tag{4}
\end{align*}
$$

[^0]Note that matrix $H_{k}$, which satisfies $d_{k}=-H_{k} g_{k}$, is different from matrix $H_{\tilde{m}}^{k+1}$ in the last update (4) in general; among others since matrix $H_{k}$ is created by updating of matrix $H_{0}^{k}=\left(b_{k-1} /\left|y_{k-1}\right|^{2}\right) I$, not $H_{0}^{k+1}=\left(b_{k} /\left|y_{k}\right|^{2}\right) I$. Thus $H_{\tilde{m}}^{k+1} g_{k} \neq-d_{k}$ generally.

The Strang recurrences cannot be used directly for other updates from the Broyden class (see [2], [4]) than for the BFGS update (but another efficient approach is possible, see [6]). Some generalizations of the L-BFGS method are investigated in [9]. Here we focus on the approach which uses quantities from the preceding iteration.

Note that our methods do not belong to the Broyden class and has some common features with the multi-step quasi-Newton methods (see e.g. [7]).

We describe the new class of VM updates in Section 2 and the corresponding algorithm in Section 3; global convergence is treated in Section 4 and numerical results are reported in Section 5. Details and proofs of assertions can be found in [9].

## 2. The new class of methods

The Broyden class updates except for the BFGS update need calculate vector $H y$ in every iteration. This drawback can be eliminated by utilization of the quasiNewton condition $H y_{-}=s_{-}$. Although it is not satisfied in LM case, in this way we can construct efficient methods that use the same number of stored vectors and matrix by vector multiplications as the L-BFGS method, see Section 3.
Theorem 2.1. Let matrix $H$ be symmetric positive definite, $H y_{-}=s_{-}, \sigma \in(-1,1)$, $\bar{s}=s-\sigma \sqrt{b / b_{-}} s_{-}, \bar{y}=y-\sigma \sqrt{b / b_{-}} y_{-}, \bar{b}=\bar{s}^{T} y \neq 0$ and $\bar{\varrho}=\left(1-\sigma^{2}\right) b / \bar{b}$. Then update $H_{+}^{N B}$ with parameter $\sigma$ given by

$$
\begin{equation*}
H_{+}^{N B}=(\bar{\varrho} / \bar{b}) \bar{s}^{T}+\bar{V} H \bar{V}^{T}, \quad \bar{V}=I-(1 / \bar{b}) \bar{s} \bar{y}^{T} \tag{5}
\end{equation*}
$$

is positive definite and satisfies the quasi-Newton condition $H_{+}^{N B} y=s$ (for $\sigma=0$ we obtain the BFGS update and assumption $H y_{-}=s_{-}$can be omitted). If $\sigma=s^{T} y_{-} / \sqrt{b b_{-}}$ then $\bar{s}^{T} y_{-}=0, \bar{b}=\bar{s}^{T} \bar{y}$ and if also $\sigma \in(-1,1)$ and $\bar{b}>0$, then (5) represents the generalized BFGS update with nonquadratic correction parameter $\bar{\varrho}$ (see [4]), with vectors $s$ and $y$ replaced by $\bar{s}, \bar{y}$. If $\sigma=s_{-}^{T} y / \sqrt{b b_{-}}$then $s_{-}^{T} \bar{y}=0$ and $\bar{\varrho}=1$.

Our numerical experiments indicate that convergence is significantly deteriorated when $|\sigma| \rightarrow 1$ and that all values $\sigma$ satisfying $|\sigma| \leq 1 / 2$ with a suitable sign (Theorem 2.1 and Lemma 2.1 motivate us to use the sign of $s^{T} y_{-}$) give very good results.
Lemma 2.1. Let $H y_{-}=s_{-}$and $f$ be quadratic function $f(x)=\frac{1}{2}\left(x-x^{*}\right)^{T} G\left(x-x^{*}\right)$, $x^{*} \in \mathcal{R}^{N}$, with a symmetric positive definite matrix $G$. If vectors $s, s_{-}$are linearly independent and update $H_{+}^{N B}$ of matrix $H$ is given by (5) then choice $\sigma=s^{T} y_{-} / \sqrt{b b_{-}}$ (or equivalently $\sigma=s_{-}^{T} y / \sqrt{b b_{-}}$) satisfies $\bar{b}>0, \sigma \in(-1,1), \varrho=1$ and $H_{+}^{N B} y_{-}=s_{-}$.

Note that we need not calculate value $s^{T} y_{-}$. We use only the sign of $s^{T} y_{-}$, therefore in view of the following lemma we can utilize the value $s_{-}^{T} g$, computed during the line search procedure, in spite of the fact that assumption $d=-H g$ is not appropriate to LM updates, see Section 1. In Section 3 we describe a choice of the sign of $\sigma$ in details.

Lemma 2.2. Let $H$ be nonsingular matrix, $H y_{-}=s_{-}$. If $d=-H g$ then $s^{T} y_{-}=-t s_{-}^{T} g$.
Taking into account Theorem 2.1 and Lemma 2.1, we will choose such parameter $\sigma \in(-1,1)$ that corresponding $\bar{b}$ is positive and not too small in comparison with $b$ in a sense that $\bar{b} \equiv b\left(1-\sigma s_{-}^{T} y / \sqrt{b b_{-}}\right) \geq b(1-\lambda), \lambda \in(0,1)$, which is equivalent to $\sigma s_{-}^{T} y \leq \lambda \sqrt{b b_{-}}$. The following lemma shows that in case that $\bar{b}<b(1-\lambda)$ for some $\sigma \in(-1,1)$, we can replace this $\sigma$ by a more appropriate value.

Lemma 2.3. Let $\sigma s_{-}^{T} y>\lambda \sqrt{b b_{-}}$for some $\lambda \in(0,1)$. Then $s_{-}^{T} y \neq 0$ and value $\hat{\sigma}=\lambda \sqrt{b b_{-}} /\left|s_{-}^{T} y\right|>0$ satisfies $\pm \hat{\sigma} s_{-}^{T} y \leq \lambda \sqrt{b b_{-}}$(for both signs) and $\hat{\sigma}<|\sigma|$.

## 3. Implementation

Here we give the procedure based on Section 2. We define matrices $H_{0}^{k+1}$ and $H_{k+1}=H_{\tilde{m}+1}^{k+1}, \tilde{m}=\min (k, m-1), m \geq 1, k \geq 0$, by relations similar to (3), (4). Instead of matrices $H_{k}$, only $\tilde{m}+1 \leq m$ couples of vectors are stored here to compute the direction vector $d_{k+1}=-H_{k+1} g_{k+1}$, using the Strang recurrences, see [8], with a little modification - using transformed nonquadratic correction parameter $\bar{\varrho}$, see [4].

We choose the sign of $\sigma$ in accordance with the sign of $-t s_{-}^{T} g \approx s^{T} y_{-}$, see Lemma 2.2 and Theorem 2.1. Since $s^{T} y_{-}=s_{-}^{T} y$ for $f$ quadratic, see Lemma 2.1, we prefer the sign of $s_{-}^{T} y$ in case that $\left|t s_{-}^{T} g\right|$ is too small in comparison with $\left|s_{-}^{T} y\right|$ (constant 20 in Step 2 was found empirically). Using Lemma 2.3, we bound $|\sigma|$ to have $\bar{b}$ not too small, compared with $b$. For simplicity, we omit stopping criteria.

## Algorithm 3.1

Data: The number $m$ of VM updates per iteration, upper bound $\bar{\sigma} \in(0,1)$ for $\left|\sigma_{k}\right|$, safeguard parameter $\lambda \in(0,1)$ and line search parameters $\varepsilon_{1}$ and $\varepsilon_{2}$, $0<\varepsilon_{1}<\frac{1}{2}, \varepsilon_{1}<\varepsilon_{2}<1$.
Step 0: Initiation. Choose the starting point $x_{0} \in \mathcal{R}^{N}$, define direction vector $d_{0}=$ $-g_{0}$ and initiate iteration counter $k$ to zero.
Step 1: Line search. Compute $x_{k+1}=x_{k}+t_{k} d_{k}$, where $t_{k}$ satisfies (1), $g_{k+1}=$ $\nabla f\left(x_{k+1}\right), y_{k}=g_{k+1}-g_{k}$ and $b_{k}$.
Step 2: Update preparation. If $\left|s_{-}^{T} y\right|>20 t\left|s_{-}^{T} g\right|$ set $\nu_{k}=\operatorname{sgn}\left(s_{-}^{T} y\right)$, otherwise set $\nu_{k}=-\operatorname{sgn}\left(s_{-}^{T} g\right)$. Choose parameter $\breve{\sigma}_{k} \in[0, \bar{\sigma}]$ (for $k=0$ we choose $\breve{\sigma}_{k}=0$ ) and set $\sigma_{k}=\nu_{k} \check{\sigma}_{k}$. If $\sigma_{k} s_{-}^{T} y>\lambda \sqrt{b b_{-}}$set $\sigma_{k}=\lambda \nu_{k} \sqrt{b b_{-}} /\left|s_{-}^{T} y\right|$. Using Theorem 2.1, compute $\bar{b}_{k}, \bar{s}_{k}$ and $\bar{\varrho}_{k}$ and define $\bar{V}_{k}$.
Step 3: Update definition. Set $\tilde{m}=\min (k, m-1)$ and define $H_{0}^{k+1}=\left(b_{k} /\left|y_{k}\right|^{2}\right) I$ and $H_{k+1} \equiv H_{\tilde{m}+1}^{k+1}$ by

$$
\begin{equation*}
H_{i+1}^{k+1}=\left(\bar{\varrho}_{j} / \bar{b}_{j}\right) \bar{s}_{j} \bar{s}_{j}^{T}+\bar{V}_{j} H_{i}^{k+1} \bar{V}_{j}^{T}, \quad j=k-\tilde{m}+i, \quad 0 \leq i \leq \tilde{m} . \tag{6}
\end{equation*}
$$

Step 4: Direction vector. Set $k:=k+1$ and compute $d_{k}=-H_{k} g_{k}$ by the modified Strang recurrences, using the definition of matrices $\left\{H_{i}^{k}\right\}_{i=0}^{\min (k, m)}$, and go to Step 1.

## 4. Global convergence

Assumption 4.1. The objective function $f: \mathcal{R}^{N} \rightarrow \mathcal{R}$ is bounded from below and uniformly convex with bounded second-order derivatives (i.e. $0<\underline{G} \leq \underline{\lambda}(G(x)) \leq$ $\bar{\lambda}(G(x)) \leq \bar{G}<\infty, x \in \mathcal{R}^{N}$, where $\underline{\lambda}(G(x))$ and $\bar{\lambda}(G(x))$ are the lowest and the greatest eigenvalues of the Hessian matrix $G(x)$ ).

Since our new LM methods do not belong to the Broyden class, the usual approach must be modified. The following lemma before the main theorem plays basic role.

Lemma 4.1. Let matrix $A$ be symmetric positive definite, $\vartheta>0, \tau \neq 0, u \in \mathcal{R}^{N}$ and $v \in \mathcal{R}^{N}$. Then update $A_{+}$given by $A_{+}=\tau^{2} \vartheta u u^{T}+\left(I-\tau u v^{T}\right) A\left(I-\tau v u^{T}\right)$ is positive definite and satisfies

$$
\begin{align*}
\operatorname{Tr}\left(A_{+}\right) & \leq \tau^{2} \vartheta|u|^{2}+\operatorname{Tr}(A)(1+|\tau|(|u||v|))^{2},  \tag{7}\\
\operatorname{Tr}\left(A_{+}^{-1}\right) & \leq \operatorname{Tr}\left(A^{-1}\right)+|v|^{2} / \vartheta . \tag{8}
\end{align*}
$$

Theorem 4.1. Let objective function $f$ satisfy Assumption 4.1. Then Algorithm 3.1 generates a sequence $\left\{g_{k}\right\}$ that either terminates with $g_{k}=0$ for some $k$ or $\lim _{k \rightarrow \infty}\left|g_{k}\right|=0$.

## 5. Numerical results

First we demonstrate the influence of parameter $\sigma$ on the number of evaluations and computational time, using the collection of sparse and partially separable test problems from [5] (Test 14, 22 problems) with $N=1000, m=10, \lambda=1 / 2$ and the final precision $\left\|g\left(x^{\star}\right)\right\|_{\infty} \leq 10^{-6}$.

Results are given in Table 1, where 'NFE' is the total number of function and also gradient evaluations over all problems, 'Time' the total computational time in seconds and $\phi$ is the arithmetic mean of values 'NFE' and 'Time' over all $\sigma$.

| $\sigma$ | NFE | Time | $\sigma$ | NFE | Time |

Tab. 2: CUTE - Percentage increase of NFV against L-BFGS.
For a better comparison with the L-BFGS method, we performed additional tests with problems from the widely used CUTE collection [1] with various dimensions $N$, $m=10, \lambda=1 / 2$ and the final precision $\left\|g\left(x^{\star}\right)\right\|_{\infty} \leq 10^{-6}$. The percentage increase of NFV for various values of parameter $\sigma$ against NFV for the L-BFGS (negative values indicate that our results are better than for the L-BFGS) is given in Table 2, where NFV is the number of function and also gradient evaluations. In the last line, the total values over all problems and their percentage increase are given.

Our limited numerical experiments indicate that the suitable choice of parameter $\sigma$ can improve efficiency of limited-memory methods, substantially for some problems.
