# ON BETWEENNESS-UNIFORM GRAPHS 

Silvia Gago, Barcelona, Jana Coroničová Hurajová, Tomáš Madaras, Košice

(Received March 28, 2012)

Abstract. The betweenness centrality of a vertex of a graph is the fraction of shortest paths between all pairs of vertices passing through that vertex. In this paper, we study properties and constructions of graphs whose vertices have the same value of betweenness centrality (betweenness-uniform graphs); we show that this property holds for distanceregular graphs (which include strongly regular graphs) and various graphs obtained by graph cloning and local join operation. In addition, we show that, for sufficiently large $n$, there are superpolynomially many betweenness-uniform graphs on $n$ vertices, and explore the structure of betweenness-uniform graphs having a universal or sub-universal vertex.

Keywords: betweenness centrality; betweenness-uniform graph
MSC 2010: 05C12

## 1. Introduction

In applied graph theory, a lot of attention is paid to the analysis of complex networks that represent relations between various objects. One of typical tasks of such an analysis is the identification of objects which play a key role within the network. The measure of importance of these objects is usually expressed by the values of centrality indices. Given a graph $G$, a centrality index is a function $c$ : $V(G) \rightarrow \mathbb{R}$ which is invariant under graph isomorphism. The most frequently used centrality indices are vertex degree, eccentricity, or sum of all distances from a vertex. Another widely used centrality is the betweenness centrality (see [5]), which measures

[^0]the amount of information that flows through a network node. It is roughly defined as the fraction of shortest paths in a graph which pass through a selected vertex. More precisely, if $\sigma_{u, v}$ is the number of shortest paths with the start vertex $u$ and end vertex $v$, and $\sigma_{u, v}(x)$ is the number of these $u$ - $v$-paths passing through the vertex $x \neq u, v$, then the betweenness of $x$ is $B(x)=\sum_{(u, v) \in V^{2}} \sigma_{u, v}(x) / \sigma_{u, v}$; the symbol $\bar{B}(G)$ will stand for the average of values of betweenness of the vertices of a graph $G$. Besides practical applications, attention is recently paid also to graph-theoretical properties of betweenness centrality (see the papers [4], [11], [3], [7]), as the average betweenness centrality of an $n$-vertex graph $G$ directly depends on the mean distance $\bar{l}(G)$ by the formula $\bar{B}(G)=(n-1)(\bar{l}(G)-1)$ (see [6], [1]). The related variant of betweenness, the edge betweenness centrality (defined as the sum $\sum_{(u, v) \in V^{2}} \sigma_{u, v}(e) / \sigma_{u, v}$ where $\sigma_{u, v}(e)$ is the number of shortest $u$ - $v$-paths that pass through the edge $e$ ) was also studied mainly in connection with the detection of subgroups in social networks, see the paper [9].

According to a selected centrality index, one may consider two kinds of extremal networks: heterogeneous networks with vertices having different centralities and uniform networks with all vertices having the same centrality. For instance, if the centrality index is the vertex degree, the extremal networks would correspond to antiregular graphs (that is, graphs with just two vertices of the same degree) and regular graphs.

In this paper, we explore betweenness-uniform graphs: the graphs with vertices having the same betweenness. These graphs seem to be rare-using the graph databases provided by Brendan McKay [12] and Wolfram Mathematica 8 code for betweenness testing, we have found out that, among all connected graphs on at most 10 vertices, only 75 are betweenness-uniform (see Figure 3 with list of all such graphs on $4-10$ vertices). Yet these graphs constitute a relatively dense family-we show that, for sufficiently large integer $n$, there are superpolynomially many betweennessuniform graphs on $n$ vertices.

It is easy to see that any vertex-transitive graph is betweenness-uniform; on the contrary, we show that there are many betweenness-uniform graphs which are not vertex-transitive. Namely, we show that this property holds for the wide class of distance-regular graphs (and its subset of strongly regular graphs), which implies the existence of betweenness-uniform graphs with arbitrarily chosen automorphism groups.

As both the vertex-transitive and the distance-regular graphs are regular, we are interested in constructions of betweenness-uniform graphs which are nonregular. Particularly, we ask the following: which degree sequences may betweenness-uniform graphs possess? We present several constructions based on graph cloning and local join operation; in addition, we estimate the maximum number of distinct degrees that
a betweenness-uniform graph may have, and determine the structure of betweennessuniform graphs with a universal vertex.

Throughout this paper, we consider connected graphs without loops or multiple edges; we use the standard graph terminology as used in [2]. Given a graph $G=(V, E)$, the order and the size of $G$ is the number of vertices and edges of $G$, respectively. We denote by $\Delta(G)$ the maximum degree of $G$, and by $N(x)$ the set of neighbours of a vertex $x$ of $G$. The distance between two vertices $u$ and $v$ is the length of the shortest path between the two vertices and is denoted by $d(u, v)$; the maximum distance between the vertices of the graph $\max _{u, v \in V} d(u, v)$ is the diameter of $G, \operatorname{diam}(G)$, and we also denote $N_{i}(u)=\{v \in V: d(u, v)=i\}$. The complete graph on $n$ vertices is denoted by $K_{n}$. A real-valued function $f$ is called superpolynomial if it grows faster than any polynomial (that is, if $\lim _{x \rightarrow \infty} f(x) / x^{n}=+\infty$ for each positive integer $n$ ).

## 2. General properties

In this section, we present several results on general properties of betweennessuniform graphs.

Theorem 2.1. Each betweenness-uniform graph is 2-connected.
Proof. By contradiction. Let $G$ be a betweenness-uniform graph which is not 2-connected, and let $H_{1}$ be an endblock of $G$ (that is, a block which contains only one cutvertex) with the minimum number $h_{1}+1$ of vertices. Let $x$ be the cut-vertex of $G$ which belongs to $H_{1}$, let $H_{2}, \ldots, H_{k}$ be components of $G-x$ which are different from $H_{1}$, let $h_{i}=\left|V\left(H_{i}\right)\right|$ for $i=2, \ldots, k$, and let $y$ be the vertex with the maximum distance from $x$ in $H_{1}$. It is easy to see that $h_{1} \geqslant 2$. Now $B(x) \geqslant 2 \sum_{\substack{i, j=1 \\ i<j}}^{k} h_{i} h_{j}$ (since any pair of vertices from distinct components $H_{i}, H_{j}$ contributes at least 1 to the sum for $B(x))$. On the other hand, if $u \in V\left(H_{i}\right), v \in V\left(H_{j}\right), H_{i} \neq H_{j} \neq H_{1}$ or $u \in V\left(H_{i}\right), v \in V\left(H_{1}\right), i \neq 1$, then the pair $(u, v)$ does not contribute to the sum for $B(y)$. We conclude that the only pairs contributing to the sum for $B(y)$ are the ones consisting of vertices of $H_{1}$ (excluding the vertex $y$ ). Therefore, using the fact that the betweenness of a vertex in an $n$-vertex graph is at most $(n-1)(n-2)$ (see $[7])$, we obtain

$$
B(y) \leqslant h_{1}\left(h_{1}-1\right)<h_{1}^{2}<2 \sum_{\substack{i, j=1 \\ i<j}}^{k} h_{i} h_{j} \leqslant B(x),
$$

a contradiction.

Lemma 2.1. Let $G$ be a graph of diameter 2. Then for every vertex $x \in V(G)$, $B(x)=\sum_{\substack{(u, v) \in N^{2}(x) \\ u v \notin E(G)}} 1 / \sigma_{u, v}$.

Proof. By definition,

$$
\begin{align*}
B(x)= & \sum_{\substack{(u, v) \in V^{2}(G) \\
u, v \neq x}} \frac{\sigma_{u, v}(x)}{\sigma_{u, v}}=\sum_{(u, v) \in N^{2}(x)} \frac{\sigma_{u, v}(x)}{\sigma_{u, v}} \\
& +\sum_{(u, v) \in(V(G) \backslash N(x))^{2}} \frac{\sigma_{u, v}(x)}{\sigma_{u, v}}+\sum_{\substack{(u, v): u \in N(x), v \notin N(x)}} \frac{\sigma_{u, v}(x)}{\sigma_{u, v}}
\end{align*}
$$

Now, if both $u, v \notin N(x)$, then each $u$ - v-path containing $x$ has length 4 ; since $d(u, v) \leqslant 2$, we get $\sigma_{u, v}(x)=0$. If $u \in N(x), v \notin N(x)$ and $u v \in E(G)$, then trivially $\sigma_{u, v}(x)=0$; if $u v \notin E(G)$, then $d(u, v)=2$ but each $u$ - $v$-path passing through $x$ has length 3 , so again $\sigma_{u, v}(x)=0$. Hence, in $(\star)$, the second and third sums are equal to zero. Moreover, since $\sigma_{u, v}(x)=1$ for nonadjacent $u, v \in N(x)$ and 0 for adjacent ones, the result holds.

Lemma 2.2. Let $G$ be a betweenness-uniform graph of diameter 2, order $n$ and size $e$. Then for any $x \in V(G), B(x)=n-1-2 e / n$.

Proof. By the previous lemma, $B(x)=\sum_{\substack{(u, v) \in N^{2}(x) \\ u v \notin E(G)}}\left(1 / \sigma_{u, v}\right)$. Then in the sum $\sum_{x \in V(G)} B(x)$, each pair $(u, v)$ of nonadjacent vertices contributes $1 / \sigma_{u, v}$ to each of their common neighbours; for this pair, there are $\sigma_{u, v}$ common neighbours, hence, we obtain

$$
\sum_{x \in V(G)} B(x)=\sum_{\substack{(u, v) \in V^{2}(G) \\ u v \notin E(G)}} \sigma_{u, v} \cdot \frac{1}{\sigma_{u, v}}=\sum_{\substack{(u, v) \in V^{2}(G) \\ u v \notin E(G)}} 1=n(n-1)-2 e
$$

and thus, for any $x \in V(G), B(x)=(1 / n) \sum_{y \in V(G)} B(y)=n-1-2 e / n$.
Now we turn our attention to degree sequences of betweenness-uniform graphs and the possible values of betweenness that the vertices of betweenness-uniform graphs may reach. Our first result shows that a non-complete betweenness-uniform graph does not contain a universal vertex (that is, a vertex adjacent to every other vertex):

Theorem 2.2. Let $G$ be an $n$-vertex betweenness-uniform graph with $\Delta(G)=$ $n-1$. Then $G \cong K_{n}$.

Proof. Let $x$ be a vertex of $G$ with $d(x)=n-1$ and let $H=G-x, V_{H}=V(H)$. Let $S=\left\{(u, v) \in V_{H}^{2}: d_{H}(u, v) \geqslant 3\right\}, T=\left\{(u, v) \in V_{H}^{2}: d_{H}(u, v)=2\right\}$ and let $\sigma_{u, v}^{\prime}$ be the number of shortest $u$-v-paths in $H$. Observe that if $(u, v) \in S$, then there is a unique shortest $u$-v-path in $G$ of length 2 , and this path contains $x$; further, if $(u, v) \in T$, then, among all $u$-v-paths of length 2 in $G$, only one contains $x$.

We obtain

$$
\begin{aligned}
& B(x)=\sum_{(u, v) \in S} \frac{\sigma_{u, v}(x)}{\sigma_{u, v}}+\sum_{(u, v) \in T} \frac{\sigma_{u, v}(x)}{\sigma_{u, v}}=\sum_{(u, v) \in S} 1+\sum_{(u, v) \in T} \frac{1}{\sigma_{u, v}^{\prime}+1}, \\
& B(y)=\sum_{(u, v) \in S} \frac{\sigma_{u, v}(y)}{\sigma_{u, v}}+\sum_{(u, v) \in T} \frac{\sigma_{u, v}(y)}{\sigma_{u, v}}=\sum_{(u, v) \in S} 0+\sum_{\substack{(u, v) \in T \\
u y, v y \in E(H)}} \frac{1}{\sigma_{u, v}^{\prime}+1} .
\end{aligned}
$$

Since $G$ is betweenness-uniform, $B(x)=B(y)$, thus,

$$
\sum_{(u, v) \in S} 1+\sum_{(u, v) \in T} \frac{1}{\sigma_{u, v}^{\prime}+1}=\sum_{\substack{(u, v) \in T \\ u y, v y \in E(H)}} \frac{1}{\sigma_{u, v}^{\prime}+1}
$$

This implies that $S=\emptyset$ and every vertex of $H$ is a common neighbour of any two non-adjacent vertices in $H$. Now, if there exists a vertex $y \neq x$ which is of degree $<n-1$, then we obtain

$$
\begin{aligned}
B(x) & =\sum_{(u, v) \in T} \frac{1}{\sigma_{u, v}^{\prime}+1}=\sum_{(u, v) \in T} \frac{1}{(n-3)+1}=\frac{1}{n-2}|2 E(\bar{H})| \\
B(y) & =\sum_{\substack{(u, v) \in T \\
u y, v y \in E(H)}} \frac{1}{\sigma_{u, v}^{\prime}+1}=\sum_{\substack{(u, v) \in T \\
u y, v y \in E(H)}} \frac{1}{(n-3)+1}<\frac{1}{n-2}|2 E(\bar{H})|
\end{aligned}
$$

(since $y$ is non-adjacent to at least one vertex). Hence $B(x) \neq B(y)$, a contradiction.
Thus, in $H$, each vertex has degree $n-1$ and we obtain that $G \cong K_{n}$.
The results in Section 3 show that there exists a wide variety of non-isomorphic betweenness-uniform graphs with a sub-universal vertex (that is, a vertex which is adjacent to all but one vertex); nevertheless, we can show

Theorem 2.3. Let $G$ be an $n$-vertex betweenness-uniform graph with $\Delta(G)=$ $n-2$. Then $\operatorname{diam}(G)=2$.

Proof. Let $u$ be a vertex of $G$ of degree $n-2, N(u)=\left\{v_{1}, \ldots, v_{n-2}\right\}$, and let $w$ be a vertex of $G$ which is not adjacent to $u$. Since $G$ is connected, there exists $s \in\{1, \ldots, n-2\}$ such that $v_{s} w \in E(G)$; this implies that $\operatorname{diam}(G) \leqslant 3$.

Now,

$$
B(u)=\sum_{\substack{v_{i}, v_{j} \in N(u) \\ v_{i} v_{j} \notin E(G)}} \frac{1}{\sigma_{v_{i}, v_{j}}}+\sum_{\substack{v_{i} \in N(u) \\ d\left(v_{i}, w\right)=3}} \frac{\sigma_{v_{i}, w}(u)}{\sigma_{v_{i}, w}} \geqslant \sum_{\substack{v_{i}, v_{j} \in N(u) \cap N(w) \\ v_{i} v_{j} \notin E(G)}} \frac{1}{\sigma_{v_{i}, v_{j}}}=B(w) .
$$

Since $G$ is betweenness-uniform and $N(u) \cap N(w) \subset N(u)$, we obtain that

$$
\sum_{\substack{v_{i} \in N(u) \\ d\left(v_{i}, w\right)=3}} \sigma_{v_{i}, w}(u) / \sigma_{v_{i}, w}=0 \text { and } \sum_{\substack{v_{i}, v_{j} \in N(u) \\ v_{i} v_{j} \notin E(G)}} 1 / \sigma_{v_{i}, v_{j}}=\sum_{\substack{v_{i}, v_{j} \in N(u) \cap N(w) \\ v_{i} v_{j} \notin E(G)}} 1 / \sigma_{v_{i}, v_{j}}
$$

Thus, if $v_{i} v_{j} \notin E(G)$, then $v_{i}, v_{j} \in N(w)$.
Consider a vertex $v_{k} \in N(u)$. If $v_{k} \in N(w)$, then $d\left(v_{k}, w\right)=1$; otherwise, either for each $i \in\{1, \ldots, n-2\} \backslash\{k\}, v_{k} v_{i} \in E(G)$ (this, however, gives $v_{k} v_{s} \in E(G)$ and, subsequently, $d\left(v_{k}, w\right)=2$ ), or there is $v_{j} \in N(u)$ such that $v_{k} v_{j} \notin E(G)$ (but this gives $\left.v_{k} \in N(w)\right)$. In any case, we obtain $\operatorname{diam}(G)=2$.

Now we turn our attention to values of betweenness that the vertices of between-ness-uniform graphs may possess; for a betweenness-uniform graph $G$, let $B(G)$ denote the common value of the betweenness of its vertices.

Lemma 2.3. For any betweenness-uniform graph $G, B(G)=0$ or $B(G) \geqslant 1$.
Proof. Fix the number $n$ of vertices of a betweenness-uniform graph $G$. Then the maximum possible number of edges of $G$ is $\binom{n}{2}$ for $G \cong K_{n}$; in this case, $B(G)=0$.

Let $H$ be an $n$-vertex betweenness-uniform graph with the second highest number of edges. By Theorem 2.2, $\Delta(H) \leqslant n-2$, which implies that $|E(H)| \leqslant\binom{ n}{2}-\frac{n}{2}$ and the equality is attained if and only if $n=2 k$ and $H$ is isomorphic to the graph $K_{2 k}-k K_{2}$ of $k$-dimensional hyperoctahedron. Further, we use Theorem 2 from [7]: if a graph $G_{2}$ is the spanning subgraph of a graph $G_{1}$, then $\bar{B}\left(G_{1}\right) \leqslant$ $\bar{B}\left(G_{2}\right)-2\left(\left|E\left(G_{1}\right)\right|-\left|E\left(G_{2}\right)\right|\right) / n$.

We distinguish two cases:
(1) Let $n=2 k$. From the above findings, it follows that each $n$-vertex betweennessuniform graph different from $K_{n}$ has at least $n / 2$ edges less than $K_{n}$, hence

$$
B(G)=\bar{B}(G) \geqslant \bar{B}\left(K_{n}\right)+\frac{2\left(\left|E\left(K_{n}\right)\right|-|E(G)|\right)}{n} \geqslant 0+\frac{2 n / 2}{n}=1 .
$$

(2) Let $n=2 k+1$. Then

$$
B(G)=\bar{B}(G) \geqslant \bar{B}\left(K_{n}\right)+\frac{2\left(\left|E\left(K_{n}\right)\right|-|E(G)|\right)}{n} \geqslant 0+\frac{2(n+1) / 2}{n}=1+\frac{1}{n}>1 .
$$

We do not know an example of a betweenness-uniform graph with betweenness belonging to (1,3/2); we conjecture that, for any rational number $\alpha \in(3 / 2, \infty)$, there exists a betweenness-uniform graph with betweenness centrality equal to $\alpha$.

Next, we determine the betweenness of vertices of distance-regular graphs. Recall that a graph $G$ is distance-regular if, for any two vertices $u$ and $v$ at distance $i$, the number of vertices at distance $j$ from $u$ and at distance $i-j$ from $v$ is the same; in other words, the number $p_{i j}=\left|N_{i}(u) \cap N_{j}(v)\right|, i, j=1, \ldots, D=\operatorname{diam}(G)$, does not depend on $u$ and $v$. For a distance-regular graph $G$, one also defines a matrix (called the intersection array of $G$ )

$$
i(G)=\left\{\begin{array}{ccccc}
- & c_{1} & \ldots & c_{D-1} & c_{D} \\
a_{0} & a_{1} & \ldots & a_{D-1} & a_{D} \\
b_{0} & b_{1} & \ldots & b_{D-1} & -
\end{array}\right\},
$$

where $c_{k}=\left|N_{k-1}(u) \cap N(v)\right|, a_{k}=\left|N_{k}(u) \cap N(v)\right|$ and $b_{k}=\left|N_{k+1}(u) \cap N(v)\right|$, for any two vertices $u$, $v$ of $G, 0 \leqslant k \leqslant D$.

Theorem 2.4. Every distance regular graph is betweenness-uniform.
Proof. Let $G$ be a distance-regular graph and $w$ an arbitrary vertex of $G$ lying on a shortest path between two vertices $u, v$ with the distance $d(u, v)=k$. Suppose that $d(u, w)=l$. By induction on $k$, it is easy to prove that $\sigma_{u v}=\prod_{i=1}^{k} c_{i}$. Thus

$$
b_{u, v}(w)=\frac{\sigma_{u, v}(w)}{\sigma_{u, v}}=\frac{\sigma_{u, w} \sigma_{w, v}}{\sigma_{u, v}}=\frac{\prod_{i=1}^{l} c_{i} \prod_{i=1}^{k-l} c_{i}}{\prod_{i=1}^{k} c_{i}}=\frac{\prod_{i=1}^{l} c_{i}}{\prod_{i=k-l}^{k} c_{i}}
$$

This means that the betweenness does not depend on the choice of vertices $u, v$, just on the distance between them. Moreover, $B(w)=\sum_{u, v \neq w} b_{u, v}(w)$ does not depend on $w$, hence, it is the same for all vertices of $G$.

In particular, every strongly regular graph is distance-regular, and therefore betweenness-uniform. This provides the existence of betweenness-uniform nontransitive graphs, according to theorem of Phelps:

Theorem 2.5 ([10]). For each finite group $A$ there exists a strongly regular graph with the automorphism group isomorphic to $A$.

Corollary 2.1. For each finite group $A$ there exists a betweenness-uniform graph whose automorphism group is isomorphic to $A$.

## 3. Constructions of betweenness-uniform graphs

In this section, we study betweenness-uniform nonregular graphs; we present constructions which yield betweenness-uniform graphs having vertices of several different degrees by using the operation of graph cloning (see, for example, [8]).

Let $G$ be a graph with the vertex set $\left\{v_{1}, \ldots, v_{n}\right\}$ and let $H_{1}, \ldots, H_{n}$ be other graphs. The graph $G\left[H_{1}, \ldots, H_{n}\right]$ is obtained from $G$ by replacing each vertex $v_{i}$ in $G$ by $H_{i}$ and taking a join on $H_{i}$ and $H_{j}$ whenever $v_{i} v_{j}$ is an edge of $G$ (see Figure 1); for $H_{1}=\ldots=H_{n}=H$, we write $G[H]$ for short. The subgraph $H_{i}$ in $G\left[H_{1}, \ldots, H_{n}\right]$ resulting from the above described replacement will be called the substitute for $v_{i}$.

Figure 1. An example of graph cloning
Theorem 3.1. Let $G$ be a betweenness-uniform graph and $m$ an integer. Then $G\left[K_{m}\right]$ is betweenness-uniform.

Proof. Let $x$ be an arbitrary vertex of $G\left[K_{m}\right]$ and $x_{t}$ the vertex of $G$ that corresponds to the substitute $K^{t} \cong K_{m}$ in $G\left[K_{m}\right]$. Let $u \in K^{i}, v \in K^{j}$ be two distinct vertices of $G\left[K_{m}\right]$ (different from $x_{t}$ ) and let $u_{i}, v_{j}$ be the vertices in $G$ that correspond to the substitutes $K^{i}, K^{j}$. Now, $d_{G\left[K_{m}\right]}(u, v)=d_{G}\left(u_{i}, v_{j}\right)=d, \sigma_{u, v}=\sigma_{u_{i}, v_{j}} m^{d-1}$ (each fixed shortest $u_{i}$ - $v_{j}$-path of length $d$ in $G$ results in $m^{d-1}$ shortest $u$ - v-paths in $\left.G\left[K_{m}\right]\right)$ and if $d_{G}\left(u_{i}, x_{l}\right)=h, d_{G}\left(x_{l}, v_{j}\right)=k$, then $\sigma_{u, v}(x)=m^{h-1} m^{k-1} \sigma_{u_{i}, v_{j}}\left(x_{t}\right)=$
$\sigma_{u_{i}, v_{j}}\left(x_{t}\right) m^{h+k-2}=\sigma_{u_{i}, v_{j}}\left(x_{t}\right) m^{d-2}$ (any shortest $u$ - $v$-path passing through $x$ corresponds to some shortest $u_{i}-v_{j}$-path passing through $x_{t}$ ). Hence, we obtain

$$
\begin{aligned}
B_{G\left[K_{m}\right]}(x)= & \sum_{(u, v) \in V^{2}\left(G\left[K_{m}\right]\right)} \frac{\sigma_{u, v}(x)}{\sigma_{u, v}}=\sum_{(u, v) \in V^{2}\left(G\left[K_{m}\right]\right)} \frac{m^{d-2} \sigma_{u_{i}, v_{j}}\left(x_{t}\right)}{m^{d-1} \sigma_{u_{i}, v_{j}}} \\
= & \frac{1}{m} \sum_{(u, v) \in V^{2}\left(G\left[K_{m}\right]\right)} \frac{\sigma_{u_{i}, v_{j}}\left(x_{t}\right)}{\sigma_{u_{i}, v_{j}}}=\frac{1}{m} \sum_{\substack{(u, v) \in V^{2}\left(G\left[K_{m}\right]\right) \\
u \in K^{i}, v \in K^{j}}} \frac{\sigma_{u_{i}, v_{j}}\left(x_{t}\right)}{\sigma_{u_{i}, v_{j}}} \\
& =\frac{1}{m} \sum_{\left(u_{i}, v_{j}\right) \in V^{2}(G)} m \cdot m \cdot \frac{\sigma_{u_{i}, v_{j}}\left(x_{t}\right)}{\sigma_{u_{i}, v_{j}}}=m \sum_{\left(u_{i}, v_{j}\right) \in V^{2}(G)} \frac{\sigma_{u_{i}, v_{j}}\left(x_{t}\right)}{\sigma_{u_{i}, v_{j}}}=m B_{G}\left(x_{t}\right)
\end{aligned}
$$

which is independent of $x$ due to the fact that $G$ is betweenness-uniform.
Theorem 3.2. Let $G$ be a betweenness-uniform $k$-regular graph and let $H=$ $\bigcup_{i=1}^{l} n_{i} K_{r_{i}}$ be a disjoint union of $n_{i}$ complete graphs of orders $r_{i}, i=1, \ldots, l$. Then $G[H]$ is betweenness-uniform.

Proof. Put $m=\sum_{i=1}^{l} n_{i} r_{i}$. Let $x$ be an arbitrary vertex of $G[H]$ and $x_{t}$ the vertex of $G$ that corresponds to a substitute $H^{t} \cong H$ in $G[H]$. Let $u \in H^{i}, v \in H^{j}$ be two distinct nonadjacent vertices of $G[H]$ (different from $x$ ) and let $u_{i}, v_{j}$ be vertices in $G$ that correspond to the substitutes $H^{i}, H^{j}$. If $i \neq j$ then, like in the previous proof, $d_{G[H]}(u, v)=d_{G}\left(u_{i}, v_{j}\right)=d, \sigma_{u, v}=\sigma_{u_{i}, v_{j}} m^{d-1}$ and if $d_{G}\left(u_{i}, x_{l}\right)=h, d_{G}\left(x_{l}, v_{j}\right)=p$, then $\sigma_{u, v}(x)=m^{h-1} m^{p-1} \sigma_{u_{i}, v_{j}}\left(x_{t}\right)=\sigma_{u_{i}, v_{j}}\left(x_{t}\right) m^{h+p-2}=\sigma_{u_{i}, v_{j}}\left(x_{t}\right) m^{d-2}$. If $i=j$ then $\sigma_{u, v}=k m$ and $\sigma_{u, v}(x)=1$. Hence, we obtain

$$
\begin{aligned}
B_{G[H]}(x)= & \sum_{(u, v) \in V^{2}(G[H])} \frac{\sigma_{u, v}(x)}{\sigma_{u, v}}=\sum_{\substack{(u, v) \in V^{2}(G[H]) \\
u \in H^{i}, v \in H^{j}, i \neq j}} \frac{m^{d-2} \sigma_{u_{i}, v_{j}}\left(x_{t}\right)}{m^{d-1} \sigma_{u_{i}, v_{j}}} \\
& +\sum_{\substack{(u, v) \in V^{2}(G[H]) \\
u, v \in H^{i}}} \frac{\sigma_{u, v}(x)}{\sigma_{u, v}}=\frac{1}{m} \sum_{\substack{(u, v) \in V^{2}(G[H]) \\
u \in H^{i}, v \in H^{j}, i \neq j}} \frac{\sigma_{u_{i}, v_{j}}\left(x_{t}\right)}{\sigma_{u_{i}, v_{j}}} \\
& +k \cdot 2\left(\binom{m}{2}-\sum_{i=1}^{l} n_{i}\binom{r_{i}}{2}\right) \cdot \frac{1}{k m} \\
= & \frac{1}{m} \sum_{\left(u_{i}, v_{j}\right) \in V^{2}(G)} m \cdot m \cdot \frac{\sigma_{u_{i}, v_{j}}\left(x_{t}\right)}{\sigma_{u_{i}, v_{j}}}+\frac{1}{m}\left(m(m-1)-\sum_{i=1}^{l} n_{i} r_{i}\left(r_{i}-1\right)\right) \\
= & m B_{G}(x)+m-1+\sum_{i=1}^{l} n_{i} r_{i}\left(r_{i}-1\right) / m .
\end{aligned}
$$

Since $G$ is betweenness-uniform, this expression does not depend on $x$.
This result provides a lower bound of order $\Omega(\sqrt{n})$ for the maximum possible number of distinct degrees (the graph diversity) of an $n$-vertex betweenness-uniform graph: setting $G \cong K_{2}$ and $H \cong \bigcup_{i=1}^{t} K_{i}$, one obtains the betweenness-uniform graph $G[H]$ with $2 \sum_{i=1}^{t} i=t(t+1)$ vertices and $t$ distinct degrees $t(t+1) / 2+i, i=0, \ldots, t-1$; with $t(t+1)=n$, we have $t=(\sqrt{4 n+1}-1) / 2$. For $n \geqslant 4$, an easy upper bound $n-3$ can be deduced from Theorem 2.2 and the fact that an $n$-vertex graph with the maximum degree $n-2$ and $n-2$ distinct degrees contains a vertex of degree 1 , but its betweenness is zero. It is an open question whether the upper bound for the diversity of a betweenness-uniform graph is a sublinear function in terms of the number of vertices.

Theorem 3.2 can be also used to show the following

Corollary 3.1. There exists an integer $N$ such that, for each even integer $n \geqslant$ $N$, there exist superpolynomially many nonisomorphic nontransitive betweennessuniform graphs on $n$ vertices.

Proof. Put $n=2 k$ and consider an integer partition $k=k_{1}+\ldots+k_{l}$. Let $H$ be a disjoint union of complete graphs of orders $k_{i}, i=1, \ldots, l$ and let $G \cong K_{2}$. By the previous theorem, $G[H]$ is betweenness-uniform. Also, it is easy to see that, using this construction, different number partitions yield nonisomorphic resulting graphs. Thus, the number of $n$-vertex nonisomorphic betweenness-uniform graphs is at least the number of integer partitions $p(k)$ of the number $k=n / 2$, which is superpolynomial in $k$ by Hardy-Ramanujan formula $p(k) \sim(4 k \sqrt{3})^{-1} \mathrm{e}^{\pi \sqrt{2 k / 3}}$. Note also that for fixed $k$, the number of integer partitions of $k$ with equal parts is sublinear in $k$, and any partition of $k$ with at least two distinct parts yields a betweennessuniform graph $G[H]$ which is not vertex transitive; hence, the number of nontransitive graphs arisen from the above construction is also superpolynomial in $k$.

The constructions of Theorems 3.1 and 3.2 are based on cloning betweennessuniform graphs with complete graphs or disjoint unions of complete graphs. However, betweenness-uniform graphs can be also constructed by using clonings of any kind of graph, by replacing vertices with different complete graphs, as can be seen in the next

Theorem 3.3. Let $s, m, n$ be integers and let $G$ be the graph obtained from two disjoint copies $K^{1}, K^{2}$ of $K_{s}$ on vertices $u_{1}, \ldots, u_{s}$ and $v_{1}, \ldots, v_{s}$, respectively, by adding edges $u_{i} v_{i}$ for each $i=1, \ldots, s$. Then the graph $G^{\prime}=G\left[K_{m}, \ldots, K_{m}\right.$,
$\left.K_{n}, \ldots, K_{n}\right]$ (where the replacement by $K_{m}$ is applied on $u_{1}, \ldots, u_{s}$ ) is betweennessuniform.

Proof. It is easy to see that the diameter of $G$ is 2 . Denote by $\left(A_{1}, \ldots, A_{s}\right)$ and $\left(B_{1}, \ldots, B_{s}\right)$ the partitions of $V\left(K^{1}\right)$ and $V\left(K^{2}\right)$ such that $A_{i}$ and $B_{j}$ are vertex sets of substitutes isomorphic to $K_{m}$ and $K_{n}$, respectively, in $G^{\prime}$.

Let $x$ be a vertex of $G^{\prime}$; without loss of generality, let $x \in A_{i}$ (the case $x \in V\left(K^{2}\right)$ is similar). Then $N(x)=V\left(K^{1}\right) \cup B_{i}$. For a pair $(u, v)$ of nonadjacent vertices of $G^{\prime}, \sigma_{u, v}=m+n$. Count now the pairs $(u, v)$ of nonadjacent vertices $u, v \in N(x)$ : we obtain that one of $u, v$ is from $V\left(K^{1}\right) \backslash A_{i}$ and the other one is from $B_{i}$. Thus, there are $2(s m-m) n=2 m n(s-1)$ such pairs.

Thus, by Lemma 2.1,

$$
B(x)=\sum_{\substack{(u, v) \in N^{2}(x) \\ u v \notin E\left(G^{\prime}\right)}} \frac{1}{\sigma_{u, v}}=\sum_{\substack{(u, v) \in N^{2}(x) \\ u v \notin E\left(G^{\prime}\right)}} \frac{1}{m+n}=\frac{2 m n(s-1)}{m+n},
$$

which is independent of the choice of $x$.

Figure 2. The construction from Theorem 3.2 (grey strips correspond to bunches of edges in local joins)

Thus, we see that the operation of cloning provides, under appropriate choice of the basic graph and the substitutes, a wide variety of betweenness-uniform graphs. We believe that the underlying global structure of cloned betweenness-uniform graphs can be chosen in an arbitrary way:

Conjecture 3.1. For any graph $G$ on a vertex set $\left\{v_{1}, \ldots, v_{n}\right\}$ there exist graphs $H_{1}, \ldots, H_{n}$ such that $G\left[H_{1}, \ldots, H_{n}\right]$ is betweenness-uniform.

To provide a partial support for this conjecture, we examine betweenness-uniform graphs obtained by cloning from graphs from selected graph families.

Theorem 3.4. The graph $C_{4}\left[K_{a}, K_{b}, K_{c}, K_{d}\right]$ is betweenness-uniform if and only if $b d(b+d)=a c(a+c)$.

Proof. It is easy to calculate that, for $x$ being a vertex of a substitute $K_{a}$ or $K_{c}$ in $C_{4}\left[K_{a}, K_{b}, K_{c}, K_{d}\right]$, we have $B(x)=2 b d \cdot 1 /(a+c)$, and if $x$ is a vertex of a substitute $K_{b}$ or $K_{d}$, then $B(x)=2 a c \cdot 1 /(b+d)$; the theorem follows.

By numerical calculations, one can check that there exist many quadruples of four distinct integers $a, b, c, d$ satisfying the above condition.

Theorem 3.5. The graph $C_{5}\left[K_{a}, K_{b}, K_{c}, K_{d}, K_{e}\right]$ is betweenness-uniform if and only if $a=b=c=d=e$.

Proof. By straightforward calculation, we obtain that the betweenness of a vertex $x$ which is a vertex of a substitute of $K_{a}, K_{b}, K_{c}, K_{d}$ and $K_{e}$ in $C_{5}\left[K_{a}, K_{b}, K_{c}, K_{d}, K_{e}\right]$ are $2 b e / a, 2 a c / b, 2 b d / c, 2 c e / d$ and $2 a d / e$, respectively; puting these values equal and forming the corresponding four equations, it can be easily verified that the only solution is $a=b=c=d=e$.

The conditions obtained for the existence of betweenness-uniform clones from longer cycles are less simple. For example, in $C_{6}\left[K_{a}, K_{b}, K_{c}, K_{d}, K_{e}, K_{f}\right]$, the betweenness of vertices from the substitute $K_{a}$ is equal to $b f / a+b /(a b+d e)+$ $f /(a f+c d)$ (the other betweenness values can be obtained by cyclic shifting of the variables $a, \ldots, f$ in this expression). It is an open question whether there exists a nontrivial solution of the system of five equations formed from comparison of these betweenness values; by numerical calculations, we verified that the only solutions with all six parameters $a, \ldots, f$ being less than 20 are only those with all parameters equal.

Theorem 3.6. Let $r, s$ be integers and let $K_{r, s}=\left(\left\{x_{1}, \ldots, x_{r}\right\},\left\{y_{1}, \ldots, y_{s}\right\}, E\right)$ be a complete bipartite graph. Then $K_{r, s}\left[K_{a_{1}}, \ldots, K_{a_{r}} ; K_{b_{1}}, \ldots, K_{b_{s}}\right]$ is betweennessuniform if and only if

$$
\left(\sum_{i=1}^{r} a_{i}\right)\left(\sum_{\substack{i, j=1 \\ i<j}}^{r} a_{i} a_{j}\right)=\left(\sum_{i=1}^{s} b\right)\left(\sum_{\substack{i, j=1 \\ i<j}}^{s} b_{i} b_{j}\right) .
$$

Figure 3: All betweenness-uniform graphs on 4-10 vertices (the grey graphs are not vertex transitive)

Proof. Observe that, in the resulting clone, the neighbourhood of any vertex $x$ from a substitute $K_{a_{t}}$ (for fixed $t=1, \ldots, r$ ) consists of $\sum_{j=1}^{s} b_{j}$ vertices belonging to substitutes $K_{b_{1}}, \ldots, K_{b_{s}}$ and of $a_{t}-1$ vertices from $K_{a_{t}}$; in this neighbourhood, the only missing edges are the ones between two vertices from distinct substitutes $K_{b_{p}}, K_{b_{q}}$, and there are $\sum_{i=1}^{r} a_{i}$ shortest paths between any pair of such
vertices. Thus, by Lemma 2.1, $B(x)=2\left(\sum_{\substack{i, j=1 \\ i<j}}^{s} b_{i} b_{j}\right)\left(1 / \sum_{i=1}^{r} a_{i}\right)$. By symmetry, we obtain that for any vertex $y$ from a substitute $K_{b_{t}}$ (for fixed $t=1, \ldots, s$ ), $B(x)=2\left(\sum_{\substack{i, j=1 \\ i<j}}^{r} a_{i} a_{j}\right)\left(1 / \sum_{i=1}^{s} b_{i}\right)$. Setting $B(x)=B(y)$, the result follows.

By applying this result we obtain, for example, that the graphs $K_{2,3}\left[K_{1}, K_{4} ; K_{1}\right.$, $\left.K_{1}, K_{2}\right]$ and $K_{3,7}\left[K_{1}, K_{1}, K_{4} ; K_{1}, K_{1}, K_{1}, K_{1}, K_{1}, K_{1}, K_{2}\right]$ are betweenness-uniform. However, it is not clear whether the numbers $a_{1}, \ldots, a_{r}, b_{1}, \ldots, b_{s}$ can be always found for arbitrary complete bipartite graphs.
