# AN IMPROVEMENT OF EUCLID'S ALGORITHM* 

Jan Zítko, Jan Kuřátko

#### Abstract

The paper introduces the calculation of a greatest common divisor of two univariate polynomials. Euclid's algorithm can be easily simulated by the reduction of the Sylvester matrix to an upper triangular form. This is performed by using $c$ - $s$ transformation and $Q R$-factorization methods. Both procedures are described and numerically compared. Computations are performed in the floating point environment.

## 1 Introduction

Euclid's algorithm and the corresponding manipulations with the Sylvester resultant matrix are two well-known methods for computing the greatest common divisor of two univariate polynomials. See the book [1] or the paper [4].

Theory has been developed in those papers and all practical examples included only low-degree polynomials in which the effect of computing in floating point arithmetic has not shown. That is why we have decided to work on computation of the greatest common divisor of two large-degree polynomials in this article. Many times the numerical experiments have yielded inaccurate or even wrong results caused for instance by the big differences in the absolute value of coefficients of polynomials which are calculated during Euclid's algorithm. Since the problems in real world have demanded the best possible precision on the coefficients of the greatest common divisor some of the ideas on the balancing the coefficients have been introduced in the article [5] and several others. We have developed an improvement of Euclid's algorithm in this paper, called $c-s$ transformation, which is conducted by the transformation of Sylvester matrix. The above mentioned method, described in [2], has not been published yet and its rigorous analysis has been presented in this article.

Scalars $c$ and $s$ are computed from coefficients of polynomials in every step of Euclid's algorithm and are resembled to scalars used in Givens rotation. Detailed description is given in paragraph 2 where the classic and well known Euclid's algorithm has been compared with $c-s$ transformation. Let us mention that structure of the Sylvester matrix is preserved by both methods.

We have decided to mention another interesting approach proposed in [7] which does not preserve the structure of the Sylvester matrix. This method is based on $Q R$ factorization of the Sylvester matrix or a part of the Sylvester matrix. Coefficients of the greatest common divisor can be obtained from the last non-vanishing row of

[^0]the upper triangular matrix $R$ obtaining by $Q R$-factorization. Complete description of aforementioned algorithm and numerical experiments are given in paragraph 3.

Reasonable results can be obtained if we know the degree of the greatest common divisor. In that case we know exactly where coefficients of the greatest common divisor can be found in the matrix $R$. Algorithms for determining the degree of the greatest common divisor have been studied in [3] or [6]. Those methods are not and cannot be included in this article.

All test polynomials have been computed via convolution that is why the degree of the greatest common divisor is known and used in our examples.

In this article, all numerical experiments have been carried out in double precision. We have worked with polynomials having non-trivial greatest common divisor.

## 2 Euclid's algorithm and transformations of the Sylvester matrix

Let the symbol GCD $\left(f_{0}, f_{1}\right)$ denotes the greatest common divisor of polynomials $f_{0}$ and $f_{1}$ and $\operatorname{deg}\left(f_{0}\right)$ the degree of $f_{0}$. Let

$$
\begin{align*}
& f_{0}(x)=a_{0} x^{m}+a_{1} x^{m-1}+\cdots+a_{m-1} x+a_{m},  \tag{1}\\
& f_{1}(x)=b_{0} x^{n}+b_{1} x^{n-1}+\cdots+b_{n-1} x+b_{n}, \tag{2}
\end{align*}
$$

where $m \geq n, a_{0} a_{m} \neq 0, b_{0} b_{n} \neq 0$, To illustrate the algorithm, let us consider the polynomials $f_{0}$ and $f_{1}$ of degrees 5 and 2 respectively:

$$
\begin{aligned}
& f_{0}(x)=a_{0} x^{5}+a_{1} x^{4}+a_{2} x^{3}+a_{3} x^{2}+a_{4} x+a_{5}, \\
& f_{1}(x)=b_{0} x^{2}+b_{1} x+b_{2} .
\end{aligned}
$$

The Sylvester resultant matrix $S\left(f_{0}, f_{1}\right)$ for the polynomials $f_{0}$ and $f_{1}$ of degrees $m=5$ and $n=2$ is

$$
S\left(f_{0}, f_{1}\right)=\left[\begin{array}{ccccccc}
a_{0} & a_{1} & a_{2} & a_{3} & a_{4} & a_{5} & 0 \\
0 & a_{0} & a_{1} & a_{2} & a_{3} & a_{4} & a_{5} \\
b_{0} & b_{1} & b_{2} & 0 & 0 & 0 & 0 \\
0 & b_{0} & b_{1} & b_{2} & 0 & 0 & 0 \\
0 & 0 & b_{0} & b_{1} & b_{2} & 0 & 0 \\
0 & 0 & 0 & b_{0} & b_{1} & b_{2} & 0 \\
0 & 0 & 0 & 0 & b_{0} & b_{1} & b_{2}
\end{array}\right] .
$$

We will now formulate modified Euclid's algorithm which can scale down the big differences between the coefficients of $f_{0}$ and $f_{1}$. Let us define the division $f_{0} / f_{1}$ in the following form:

$$
\begin{aligned}
& c_{0} \underbrace{\left(a_{0} x^{5}+a_{1} x^{4}+a_{2} x^{3}+a_{3} x^{2}+a_{4} x+a_{5}\right)}_{f_{0}(x)}+s_{0} \underbrace{\left(b_{0} x^{2}+b_{1} x+b_{2}\right)}_{f_{1}(x)} x^{3} \\
& =0+\underbrace{\left(c_{0} a_{1}+s_{0} b_{1}\right)}_{a_{1}^{(1)}} x^{4}+\underbrace{\left(c_{0} a_{2}+s_{0} b_{2}\right)}_{a_{2}^{(1)}} x^{3}+\underbrace{c_{0} a_{3}}_{a_{3}^{(1)}} x^{2}+\underbrace{c_{4}}_{a_{1}^{(1)} x^{4}+a_{2}^{(1)} x^{3}+a_{3}^{(1)} x^{2}+a_{4}^{(1)} x+a_{5}^{(1)}} x+\underbrace{c_{0} a_{5}}_{a_{5}^{(1)}}
\end{aligned} .
$$

The numbers $c_{0}$ and $s_{0}$ are chosen to remove the leading coefficient of $f_{0}$. To define the corresponding transformation of the Sylvester matrix, let us define the matrix $G_{0}^{(1)}\left(c_{0}, s_{0}\right)$

$$
G_{0}^{(1)}\left(c_{0}, s_{0}\right)=\left[\begin{array}{ccccccc}
c_{0} & 0 & s_{0} & 0 & 0 & 0 & 0 \\
0 & c_{0} & 0 & s_{0} & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 1
\end{array}\right] .
$$

Apparently

$$
S^{(1)}\left(f_{0}, f_{1}\right):=G_{0}^{(1)}\left(c_{0}, s_{0}\right) S\left(f_{0}, f_{1}\right)=\left[\begin{array}{ccccccc}
0 & a_{1}^{(1)} & a_{2}^{(1)} & a_{3}^{(1)} & a_{4}^{(1)} & a_{5}^{(1)} & 0 \\
0 & 0 & a_{1}^{(1)} & a_{2}^{(1)} & a_{3}^{(1)} & a_{4}^{(1)} & a_{5}^{(1)} \\
b_{0} & b_{1} & b_{2} & 0 & 0 & 0 & 0 \\
0 & b_{0} & b_{1} & b_{2} & 0 & 0 & 0 \\
0 & 0 & b_{0} & b_{1} & b_{2} & 0 & 0 \\
0 & 0 & 0 & b_{0} & b_{1} & b_{2} & 0 \\
0 & 0 & 0 & 0 & b_{0} & b_{1} & b_{2}
\end{array}\right],
$$

where

$$
a_{i}^{(1)}=\left\{\begin{array}{cc}
c_{0} a_{i}+s_{0} b_{i} & \text { for } \\
c_{0} a_{i} & i=1,2 \\
\text { otherwise }
\end{array}\right.
$$

Let $a_{1}^{(1)} \neq 0$. Then $\operatorname{deg}\left(h_{4}\right)=4$. In the opposite case, the process would be performed with the polynomial of degree less than 4 . The Euclid's algorithm proceeds according to the following schema:

$$
\begin{aligned}
& c_{1} \underbrace{\left(a_{1}^{(1)} x^{4}+a_{2}^{(1)} x^{3}+a_{3}^{(1)} x^{2}+a_{4}^{(1)} x+a_{5}^{(1)}\right)}_{h_{4}(x)}+s_{1} \underbrace{\left(b_{0} x^{2}+b_{1} x+b_{2}\right)}_{a_{3}(x):=a_{2}^{(2)} x^{3}+a_{3}^{(2)} x^{2}+a_{4}^{(2)} x+a_{5}^{(2)}} x^{2} \\
& =0+\underbrace{\left(c_{1} a_{2}^{(1)}+s_{1} b_{1}\right)}_{a_{1}^{(x)}} x^{3}+\underbrace{\left(c_{1} a_{3}^{(1)}+s_{1} b_{2}\right)}_{a_{4}^{(2)}} x^{2}+\underbrace{c_{1} a_{4}^{(1)}}_{a_{5}^{(2)}} x+\underbrace{}_{1_{1}^{(2)} a_{5}^{(1)}}
\end{aligned}
$$

The numbers $c_{1}$ and $s_{1}$ are again chosen to remove the coefficient of $x^{4}$. The corresponding matrix operation consists of the construction of the matrix $G_{1}^{(1)}\left(c_{1}, s_{1}\right)$, by analogy to the previous case, such that

$$
S^{(2)}\left(f_{0}, f_{1}\right):=G_{1}^{(1)}\left(c_{1}, s_{1}\right) S^{(1)}\left(f_{0}, f_{1}\right)=\left[\begin{array}{ccccccc}
0 & 0 & a_{2}^{(2)} & a_{3}^{(2)} & a_{4}^{(2)} & a_{5}^{(2)} & 0 \\
0 & 0 & 0 & a_{2}^{(2)} & a_{3}^{(2)} & a_{4}^{(2)} & a_{5}^{(2)} \\
b_{0} & b_{1} & b_{2} & 0 & 0 & 0 & 0 \\
0 & b_{0} & b_{1} & b_{2} & 0 & 0 & 0 \\
0 & 0 & b_{0} & b_{1} & b_{2} & 0 & 0 \\
0 & 0 & 0 & b_{0} & b_{1} & b_{2} & 0 \\
0 & 0 & 0 & 0 & b_{0} & b_{1} & b_{2}
\end{array}\right],
$$

where

$$
a_{i}^{2}=\left\{\begin{array}{ccc}
c_{1} a_{i}^{(1)}+s_{1} b_{i-1} & \text { for } & i=2,3, \\
c_{1} a_{i}^{(1)} & \text { otherwise } .
\end{array}\right.
$$

If $a_{2}^{(2)}=0$ and $a_{3}^{(2)} \neq 0$, then instead of $h_{3}$ the polynomial $h_{2}$,

$$
h_{2}(x)=a_{3}^{(2)} x^{2}+a_{4}^{(2)} x+a_{5}^{(2)},
$$

is considered. Moreover, if $a_{3}^{(2)}=0$, then the first stage of Euclid's algorithm terminates. Let us assume that the degrees of all polynomials after division decrease by 1 . Hence $a_{2}^{2} \neq 0$. Let the numbers $c_{2}, s_{2}$ and then $c_{3}$ and $s_{3}$ are chosen to remove the coefficient of dominant power. The last two divisions yield the polynomials

$$
\begin{array}{ll}
h_{2}(x)=a_{3}^{(3)} x^{2}+a_{4}^{(3)} x+a_{5}^{(3)} & =c_{2} h_{3}(x)+s_{2} f_{1}(x) x, \\
h_{1}(x)=a_{4}^{(4)} x+a_{5}^{(4)} & =c_{3} h_{2}(x)+s_{3} f_{1}(x),
\end{array}
$$

where $a_{3}^{(3)} \neq 0$ and $a_{4}^{(4)} \neq 0$. The matrices $G_{2}^{(1)}\left(c_{2}, s_{2}\right), G_{3}^{(1)}\left(c_{3}, s_{3}\right)$ correspond to the last two divisions. Their construction is omitted because it is the same as in the previous steps. If we define

$$
G_{1}=G_{3}^{(1)}\left(c_{3}, s_{3}\right) G_{2}^{(1)}\left(c_{2}, s_{2}\right) G_{1}^{(1)}\left(c_{1}, s_{1}\right) G_{0}^{(1)}\left(c_{0}, s_{0}\right)
$$

and

$$
P_{1}=\left[e_{3}, e_{4}, e_{5}, e_{6}, e_{7}, e_{1}, e_{2}\right],
$$

then the first stage of Euclid's algorithm can be written in the matrix form as follows

$$
P_{1} G_{1} S\left(f_{0}, f_{1}\right)=\left[\begin{array}{cccc:ccc}
b_{0} & b_{1} & b_{2} & 0 & 0 & 0 & 0 \\
0 & b_{0} & b_{1} & b_{2} & 0 & 0 & 0 \\
0 & 0 & b_{0} & b_{1} & b_{2} & 0 & 0 \\
0 & 0 & 0 & b_{0} & b_{1} & b_{2} & 0 \\
- & - & - & - & - & - & - \\
0 & 0 & 0 & 0 & b_{0} & b_{1} & b_{2} \\
0 & 0 & 0 & 0 & a_{4}^{(4)} & a_{5}^{(4)} & 0 \\
0 & 0 & 0 & 0 & 0 & a_{4}^{(4)} & a_{5}^{(4)}
\end{array}\right]=:\left[\begin{array}{ll}
F_{1,1} & F_{1,2} \\
F_{2,1} & F_{2,2}
\end{array}\right] .
$$

Note that we have obtained the coefficients of the polynomial $h_{1}$ in the last two rows. The formula

$$
\underbrace{c_{3} c_{2} c_{1} c_{0} f_{0}(x)}_{\tilde{f}_{0}(x)}=\underbrace{-\left(c_{3} c_{2} c_{1} s_{0} x^{3}+c_{3} c_{2} s_{1} x^{2}+c_{3} s_{2} x+s_{3}\right)}_{\tilde{q}_{0}(x)} \underbrace{f_{1}(x)}_{\tilde{f}_{1}(x)}+\underbrace{h_{1}(x)}_{\tilde{f}_{2}(x)} .
$$

summarises the first stage of Euclid's algorithm. Hence we have

$$
\widetilde{f}_{0}(x)=\widetilde{q}_{0}(x) \widetilde{f}_{1}(x)+\widetilde{f}_{2}(x)
$$

The block $F_{2,2}$ is again the Sylvester matrix $S\left(\tilde{f}_{1}, \widetilde{f}_{2}\right)$. We suppose that $\widetilde{f}_{2}(x) \neq 0$. If $\widetilde{f}_{2}(x)=0$, then $\widetilde{f}_{1}(x)=G C D\left(f_{0}, f_{1}\right)$. The transformation of the Sylvester resultant
matrix to an upper triangular matrix requires that the same procedure is applied to the matrix $S\left(\widetilde{f}_{1}, \widetilde{f}_{2}\right)$, and this corresponds to the second stage of Euclid's algorithm, that is, the division $\widetilde{f}_{1} / \widetilde{f}_{2}$. Analogously there exist matrices $G_{2}$ and $P_{2}$ such that

$$
P_{2} G_{2} P_{1} G_{1} S\left(f_{0}, f_{1}\right)=\left[\begin{array}{ccccccc}
b_{0} & b_{1} & b_{2} & 0 & 0 & 0 & 0 \\
0 & b_{0} & b_{1} & b_{2} & 0 & 0 & 0 \\
0 & 0 & b_{0} & b_{1} & b_{2} & 0 & 0 \\
0 & 0 & 0 & b_{0} & b_{1} & b_{2} & 0 \\
0 & 0 & 0 & 0 & a_{4}^{(4)} & a_{5}^{(4)} & 0 \\
0 & 0 & 0 & 0 & 0 & a_{4}^{(4)} & a_{5}^{(4)} \\
0 & 0 & 0 & 0 & 0 & 0 & b_{2}^{(2)}
\end{array}\right] .
$$

It is $\widetilde{f}_{3}(x)=b_{2}^{(2)}$. Let us remark that $\widetilde{f}_{2}(x)=G C D\left(f_{0}, f_{1}\right)$ if $\widetilde{f}_{3}(x)=0$. Otherwise $f_{0}$ and $f_{1}$ are coprime.

We will now demonstrate how to pick the numbers $c$ and $s$. If we take

$$
c_{0}=1 \quad \text { and } \quad s_{0}=-\frac{a_{0}}{b_{0}},
$$

then the division in Euclid's algorithm has the following form

$$
\begin{aligned}
& \underbrace{\left(a_{0} x^{5}+a_{1} x^{4}+a_{2} x^{3}+a_{3} x^{2}+a_{4} x+a_{5}\right)}_{f_{0}(x)}-\underbrace{\left(b_{0} x^{2}+b_{1} x+b_{2}\right)}_{f_{1}(x)}\left(\frac{a_{0}}{b_{0}}\right) x^{3} \\
& =0+\underbrace{\left(a_{1}-\frac{a_{0} b_{1}}{b_{0}}\right)}_{a_{1}^{(1)}} x^{4}+\underbrace{\left(a_{2}-\frac{a_{0} b_{2}}{b_{0}}\right)}_{a_{2}^{(1)}} x^{3}+\underbrace{a_{3}}_{a_{3}^{(1)}} x^{2}+\underbrace{a_{4}}_{a_{4}^{(1)}} x+\underbrace{a_{5}}_{a_{5}^{(1)}} .
\end{aligned}
$$

In the next step we have considered $c_{1}$ and $s_{1}$ in the form

$$
c_{1}=1 \quad \text { and } \quad s_{1}=-\frac{a_{1}^{(1)}}{b_{0}},
$$

and analogously are defined the numbers $c_{i}$ a $s_{i}$ in the following steps. This choice forms Euclid's algorithm in the well known form.

The second possible choice of $c$ and $s$ is based on the idea of balance of the coefficients of $f_{0}$ and $f_{1}$. In the first step these numbers are defined as

$$
c_{0}=\frac{b_{0}}{\sqrt{a_{0}^{2}+b_{0}^{2}}} \quad \text { and } \quad s_{0}=-\frac{a_{0}}{\sqrt{a_{0}^{2}+b_{0}^{2}}},
$$

and analogously in the next steps. This form of Euclid's algorithm will be called $c-s$ transformation. Let us denote for the polynomials (1) and (2)

$$
d_{1}=\max _{i, j \in\{1, \ldots, m\}}| | a_{i}\left|-\left|a_{j}\right|\right|, \quad d_{2}=\max _{i, j \in\{1, \ldots, n\}}| | b_{i}\left|-\left|b_{j}\right|\right|, \quad \operatorname{diff}\left(f_{0}, f_{1}\right)=\left(d_{1}, d_{2}\right) .
$$

Example 1. Let $f_{0}$ and $f_{1}$ be two polynomials such that

$$
\begin{aligned}
& f_{0}(x)=(x-4.1)(x-3)(x-\sqrt{2})^{2}(x+1)(x+\sqrt{2})(x+5)^{2}, \\
& f_{1}(x)=(x-3)(x-\sqrt{3})(x-1)(x+1)(x+\sqrt{3})(x+8) .
\end{aligned}
$$

Their greatest common divisor $u$ has the form

$$
u(x)=(x-3)(x+1)=x^{2}-2 x-3 .
$$

Let $u_{E u c}$ and $u_{c-s}$ denotes the greatest common divisor computed by Euclid's algorithm and $c$-s transformation, respectively. We have obtained

$$
\begin{aligned}
& u_{E u c}(x)=x^{2}-1.99999999999994 x-2.99999999999993 \\
& u_{c-s}(x)=x^{2}-1.99999999999998 x-2.99999999999998 \\
& \left\|u_{E u c}-u\right\|_{2}=9.26402450510883 e-14, \quad\left\|u_{c-s}-u\right\|_{2}=3.14269606124535 e-14 .
\end{aligned}
$$

Both procedures yielded practically the exact greatest common divisor. Let us remark, that for the first division $f_{0} / f_{1}$ in Euclid's algorithm we have obtained $\operatorname{diff}\left(f_{0}, f_{1}\right)=(1189.33794283234,98)$.

Example 2. Let

$$
\begin{aligned}
& f_{0}(x)=(x-4)^{2}(x-\sqrt{5})^{2}(x-\sqrt{3})^{2}(x-\sqrt{2})^{2}(x+0.5)^{2}(x+1)^{2} \\
& f_{1}(x)=(x-6.51)^{2}(x-5)^{2}(x-4)(x+0.5)^{2}(x+0.9)(x+1)^{2}
\end{aligned}
$$

Their greatest common divisor $u$ has the form

$$
u(x)=(x-4)(x+0.5)^{2}(x+1)^{2}=x^{5}-x^{4}-8.75 x^{3}-11.5 x^{2}-5.75 x-1
$$

We have obtained

$$
\begin{aligned}
& u_{E u c}(x)=x^{5}-0.9999999 x^{4}-8.75000000 x^{3}-11.5000000 x^{2}-5.75000000 x-1.00000000, \\
& u_{c-s}(x)=x^{5}-0.9999999 x^{4}-8.74999999 x^{3}-11.49999999 x^{2}-5.74999999 x-0.99999999, \\
& \left\|u_{E u c}-u\right\|_{2}=1.70205143034978 e-11, \quad\left\|u_{c-s}-u\right\|_{2}=6.36839947245598 e-12 .
\end{aligned}
$$

We have obtained again a good result. Let us remark, that for the first division $f_{0} / f_{1}$ in Euclid's algorithm we have obtained diff $\left(f_{0}, f_{1}\right)=(1116.93467622,12607.8786650)$.

Example 3. Let $f_{0}$ and $f_{1}$ be the following polynomials:

$$
\begin{aligned}
& f_{0}(x)=(x-11)^{2}(x-8)^{2}(x-6)^{2}(x-1)^{2}(x+2)^{2}(x+3)^{2} \\
& f_{1}(x)=(x-15)^{2}(x-8)(x-6)(x+5)^{2}(x+11)^{2}
\end{aligned}
$$

Their greatest common divisor $u$ has the form $u(x)=(x-8)(x-6)=x^{2}-14 x+48$.

Let us compare the result which yields the modification of Euclid's algorithm by using $c$ - $s$ transformation with the result which yields the standard implementation represented by the m-file poly_gcd. $\mathrm{m}^{1}$ denoted by $u_{\text {Euc }}$. We have obtained

$$
\begin{aligned}
& u_{E u c}(x)=x^{2}-13.99999999946275 x+47.99999999538410, \\
& u_{c-s}(x)=x^{2}-14.00000000045505 x+48.00000000093540 \\
& \left\|u_{E u c}-u\right\|_{2}=4.64705900662480 e-09 \\
& \left\|u_{c-s}-u\right\|_{2}=1.04021318800892 e-09 \\
& \operatorname{diff}\left(f_{0}, f_{1}\right)=(11024639,32669999)
\end{aligned}
$$

More examples have been calculated and we have found out that Euclid's algorithm in matrix form and $c$-s transformation yield almost the same results for low-degree polynomials, in some cases Euclid's algorithm gives better results. If the degree of both polynomials gets larger, then the $c-s$ transformation yields more accurate results.

## 3 QR factorization method for computing the greatest common divisor

The following idea described in [7] will be illustrated for the polynomials of degree $m=4$ and $n=3$. Let

$$
\begin{aligned}
& f_{0}(x)=x^{4}+a_{1} x^{3}+a_{2} x^{2}+a_{3} x+a_{4}, \\
& f_{1}(x)=b_{0} x^{3}+b_{1} x^{2}+b_{2} x+b_{3} .
\end{aligned}
$$

A companion matrix $C_{4}$ associated with the polynomial $f$ has the form

$$
C_{4}=\left[\begin{array}{cccc}
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
-a_{4} & -a_{3} & -a_{2} & -a_{1}
\end{array}\right]
$$

It is assumed that the coefficient $a_{0}=1$. The matrix $f_{1}\left(C_{4}\right)$ is very important. The $\operatorname{GCD}\left(f_{0}, f_{1}\right)$ can be obtained very easily from the matrix $f_{1}\left(C_{4}\right)$. See the book [1]. Let the Sylvester matrix be split into the four blocks

$$
S\left(f_{0}, f_{1}\right)=\left[\begin{array}{ccc:cccc}
1 & a_{1} & a_{2} & a_{3} & a_{4} & 0 & 0 \\
0 & 1 & a_{1} & a_{2} & a_{3} & a_{4} & 0 \\
0 & 0 & 1 & a_{1} & a_{2} & a_{3} & a_{4} \\
- & - & - & - & - & - & - \\
b_{0} & b_{1} & b_{2} & b_{3} & 0 & 0 & 0 \\
0 & b_{0} & b_{1} & b_{2} & b_{3} & 0 & 0 \\
0 & 0 & b_{0} & b_{1} & b_{2} & b_{3} & 0 \\
0 & 0 & 0 & b_{0} & b_{1} & b_{2} & b_{3}
\end{array}\right]=:\left[\begin{array}{cc}
S_{1,1} & S_{1,2} \\
S_{2,1} & S_{2,2}
\end{array}\right] .
$$

[^1]It is clear that all blocks are Toeplitz matrices. It is easy to calculate the Schur complement $S_{2,2}^{(*)}=S_{2,2}-S_{2,1} S_{1,1}^{-1} S_{1,2}$ and according to the well known theory $S_{2,2}^{(*)}=$ $J_{4} f_{1}\left(C_{4}\right) J_{4}$. Moreover, there exists an orthogonal matrix Q such that

$$
Q J_{4} f_{1}\left(C_{4}\right) J_{4}=R,
$$

where $J_{4}$ is a matrix with ones on the counter diagonal and $R$ is an upper-triangular matrix, the last nonzero row of which contains the coefficients of the GCD of $f_{0}$ and $f_{1}$. Let $\operatorname{GCD}\left(f_{0}, f_{1}\right)=d_{0} x^{2}+d_{1} x+d_{2}$ in our special case. Then the matrix $R$ has the form

$$
R=\left[\begin{array}{cccc}
x & x & x & x \\
0 & d_{0} & d_{1} & d_{2} \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{array}\right]
$$

where the $x$ 's indicates elements whose values are unimportant.
In the following examples let $u_{\text {Schu }}$ and $u_{\text {Hor }}$ denote the greatest common divisor which was obtained using QR-factorization of $S_{2,2}^{(*)}=S_{2,2}-S_{2,1} S_{1,1}^{-1} S_{1,2}$ and from the $Q R$-factorization of $J_{m} f_{1}\left(C_{m}\right) J_{m}$, where $f_{1}\left(C_{m}\right)$ was constructed by Horner's scheme, respectively. Let us remark that $m$ is the degree of the polynomial $f_{0}$.

Example 4. Let $f_{0}, f_{1}$ and $u$ be polynomials from Example 1. We have calculated

$$
\begin{aligned}
& u_{\text {Schu }}(x)=x^{2}-2.00000000001121 x-3.00000000001110, \\
& u_{\text {Hor }}(x)=x^{2}-2.00000000000175 x-3.00000000000208 \\
& \left\|u_{\text {Schu }}-u\right\|_{2}=1.57742694329152 e-11, \quad\left\|u_{\text {Hor }}-u\right\|_{2}=2.71252314056005 e-12 .
\end{aligned}
$$

Example 5. Let $f_{0}, f_{1}$ and $u$ be polynomials from Example 2. We have obtained

$$
\begin{aligned}
u_{\text {Schu }}(x)= & x^{5}-0.999999985809256 x^{4}-8.749999957416437 x^{3} \\
& -11.499999953695204 x^{2}-5.749999978552083 x-0.999999996447228, \\
u_{\text {Hor }}(x)= & x^{5}-1.00000000005345 x^{4}-8.75000000015926 x^{3} \\
& -11.50000000017163 x^{2}-5.75000000007888 x-1.00000000001314, \\
\left\|u_{\text {Schu }}-u\right\|_{2}= & 6.80551732665222 e-08, \quad\left\|u_{\text {Hor }}-u\right\|_{2}=2.53131658107744 e-10 .
\end{aligned}
$$

Example 6. Let $f_{0}, f_{1}$ and $u$ be the same polynomials as in Example 3. Then the following results have been calculated.

$$
\begin{aligned}
& u_{\text {Schu }}(x)=x^{2}-14.00000000217399 x+48.00000001232704, \\
& u_{\text {Hor }}(x)=x^{2}-14.00000000138107 x+48.00000000802783, \\
& \left\|u_{\text {Schu }}-u\right\|_{2}=1.25172701840642 e-08, \quad\left\|u_{\text {Hor }}-u\right\|_{2}=8.14575566893229 e-09 .
\end{aligned}
$$

The coefficients of the greatest common divisor are obtained from the 10th row of matrix $R$. Let $R$ be a matrix from $Q R$-factorization of the matrix $J_{12} f_{1}\left(C_{12}\right) J_{12}$
where $f_{1}\left(C_{12}\right)$ was constructed by Horner's scheme. The coefficients of the greatest common divisor can be obtained from the 10th row. Let us present the elements of $R$ in 9th-11th row.
row 9: $-8.32446551450895 e+05,1.13733574278167 e+07,-3.60249143760594 e+07$, $-1.34829260320804 e+07$
row 10: $-7.99170726641915 e+05,1.11883901740905 e+07,-3.83601948852275 e+07$ ( $u_{H o r}$ is obtained after transformation to monic form)
row 11: $5.13598466751748 e-03,-2.90332235929244 e-02$.
If the degree of greatest common divisor is not known, the following problem appears: Are the numbers in the 11th row zero? This difficult question is behind the topic of this short paper. For more details see [7].

## 4 Summary

Euclid's algorithm is composed from sequence of steps and division of two polynomials, whose degree is decreasing to zero, is represented in each particular step. New modification of Euclid's algorithm called $c$-s transformation has been introduced in this article. This modification produces better numerical results in comparison with classical Euclid's algorithm and it is conducted by transformation of the Sylvester matrix and structure of the Sylvester matrix is preserved. The algorithm based on $Q R$-decomposition was mentioned and its numerical results were compared with $c$ - $s$ transformation. The second algorithm does not preserve the structure of Sylvester matrix.

## Acknowledgments.
